EXECUTIVE SUMMARY

The data obtained from the ecoregion delineation and reference site monitoring project will be used as a tool to implement the requirements of the Tennessee Water Quality Control Act. The Act requires the protection of state waters and their designated uses as defined by the Tennessee Water Quality Standards. These Standards consist of three parts. The first part defines designated uses. All waters have at least the basic four uses: fish and aquatic life, recreation, irrigation, and livestock watering and wildlife. The second part establishes the general water quality criteria needed to protect those uses. The third part is the antidegradation statement, which protects existing uses of all surface waters as established under the Act. The ecoregion and reference site framework should provide scientific, practical, and defensible background data to ensure that the Water Quality Standards fully protect and maintain the waters of the state, and their designated uses.

Understanding how ecoregions affect biological health and water quality is a key step in watershed management. Reference streams serve as control streams in water quality investigations. Comparing impacted sites to ecoregion reference sites provide a tool for measuring stream quality. Monitoring impacted sites and comparing them to reference sites can also measure the progress of water quality trends within watersheds over time.

To establish values that would be representative of actual background conditions, data were collected from least disturbed and minimally impacted reference streams that were representative of an ecological region referred to as an ecoregion. Obtaining these values required delineation of ecoregion boundaries and locating ecoregion reference streams. To accomplish this goal, the Tennessee Ecoregion Delineation and Reference Site Selection Project was initiated in 1994. This project was a cooperative effort between the Tennessee Department of Environment and Conservation, Division of Water Pollution Control (WPC), the USEPA Region IV, the USEPA-National Health Environmental Effects Research Laboratory (NHEERL) and Tetra Tech Inc. Project goals consisted of the following:

1. Refine Level III ecoregions and delineate Level IV ecoregions (subregions) in Tennessee.
2. Locate least impacted and minimally disturbed reference streams in each subregion.
3. Determine baseline physical, chemical, and biological conditions in reference streams.
4. Explore the use of reference data to assist in the interpretation of existing narrative criteria.

Ecoregion delineation is a geographical framework that categorizes large sections of Tennessee into areas of similar geology, soils, physiography, land use, vegetation, climate, and water quality. Evaluation of background water quality and aquatic community health required establishment of ecoregion reference streams. These were streams considered minimally impacted and least disturbed, but were also representative of the subregion in which the stream flowed.

Delineation of Tennessee's Level III and Level IV ecoregions was completed in February 1997 with the generation of the EPA document *Ecoregions of Tennessee* (EPA/600/R-97/022). The

document described in detail the typical characteristics found in each of Tennessee's subregions. The Tennessee map illustrated eight ecoregions (Level III) and identified twenty-five subregions (Level IV).

Glenn Griffith, NHEERL, provided a list of 231 potential candidate reference sites. Site evaluations required field visits to each stream. During this initial screening process, from mid-1995 to mid-1996, additional candidate reference sites were identified resulting in a final list of 353 potential sites. During field verification, 139 sites were eliminated due to impacts. The remaining 214 sites were considered for final reference site selection. The goal was to select three reference sites per subregion. A total of 70 final reference sites was selected by August 1996.

Habitat assessments, physical measurements, chemical, and biological samples were collected at the 70 final reference sites beginning in August 1996. Biological samples were collected twice per year during the low flow period (August - October) and high flow period (March-May). Chemical samples were collected on a quarterly basis using a modified clean technique. Data were collected for three consecutive years through May 1999. During the three-year period, some initial reference sites were dropped and new ones were added depending on data results that indicated developing impacts in the watershed.

Michael Barbour and Jeffrey White of Tetra Tech Inc analyzed the first year of reference stream macroinvertebrate data, producing a report titled: *Evaluation of Tennessee Ecoregions: A Framework for Stream Classification and Bioassessment* (1998). The report addressed general water quality trends, possible seasonal effects, collection methods, metric selection, and a preliminary Tennessee Stream Condition Index (TSCI). It also included recommendations for future reference site collections.

Water quality data collected during this project were entered into the EPA Legacy STORET. Both water chemistry and biological data were entered into Microsoft Access databases. The Access databases were exported into a statistical software package. The data were displayed in standard box plots to show value ranges in each Level III and IV ecoregion. These ranges will be used to define the reference condition in each region.

ACKNOWLEDGEMENTS

The Tennessee Ecoregion Delineation Project was conducted by the Tennessee Department of Environment and Conservation (TDEC), Division of Water Pollution Control (WPC) and the EPA National Health and Environmental Effects Research Laboratory in Corvallis, Oregon. Funding was provided by a 104(b)(3) grant. Greg Denton, Joy Broach, Linda Cartwright (WPC), and Debbie Arnwine, Tennessee Department of Health (TDH), Aquatic Biology Section served as coordinators for this project.

The following individuals participated in the initial site selection and stream monitoring. Many others have been involved in continuing the project through subsequent monitoring activities.

1. INTRODUCTION

1.1 Project Background and Funding

In 1994, the Division of Water Pollution Control, Tennessee Department of Environment and Conservation, initiated an Ecoregion Delineation and Reference Site Selection Project. This long-term project was a cooperative effort between WPC, USEPA Region IV (EPA), James Omernik and Glenn Griffith, USEPA-National Health and Environmental Effects Research Laboratory (NHEERL) in Corvallis, Oregon and Michael Barbour and Jeffery White, Tetra Tech Inc. The long-term goals of the project were to:

1. Refine Level III ecoregions and delineate Level IV ecoregions (subregions) in Tennessee.
2. Locate least impacted and minimally disturbed reference streams in each subregion.
3. Determine baseline physical, chemical, and biological conditions in reference streams.
4. Explore the use of reference data to assist in the interpretation of existing narrative criteria.

The Tennessee ecoregion delineation project was initially funded with an FY1994 104(b)(3) grant. This project provided a useful geographical framework that categorized large sections of Tennessee into logical units of similar geology, soils, land use, vegetation, precipitation and water quality. One goal of this grant was to define boundaries for eight ecoregions (Level III) and twenty-five subregions (Level IV). A second goal was to develop a list of least impacted potential reference sites in each subregion. The project was completed February 1997, with publication of the EPA document *Ecoregions of Tennessee* EPA/600/R-97/022, and production of the final ecoregion map into a Geographic Information System (GIS) format.

The Ecoregion Reference Site project was divided into two phases. Phase I was funded by an FY1995 104(b)(3) grant. Phase I consisted of screening a list of 231 potential candidate reference sites located throughout the twenty-five subregions. Each site was evaluated in the field by an experienced biologist. During this screening process, additional candidates were identified resulting in 353 potential sites. One hundred and thirty nine sites were eliminated during field verification due to observable impacts. The remaining 214 sites were considered for final reference site selection. The goal was to select three reference sites in each subregion. Three were considered the minimal number necessary to provide a statistically valid database. A final list of 70 sites was selected for monitoring as potential reference streams by August 1996.

Phase II was funded by an FY1996 104 (b)(3) grant. Phase II consisted of data collection at the 70 proposed reference sites. Data consisted of habitat assessments, stream characterizations, chemical collections, and biological monitoring. Data collection began in August 1996. Biological samples were collected during the low flow period (August - October) in 1996. Chemical and bacteriological samples were collected on a quarterly basis beginning in August 1996. Funding covered chemical analyses and macroinvertebrate sample processing, identification, metric calculations, data entry, and specimen verification.

Phase IIB was a continuation of Phase II. It was funded by an FY1997 104(b)(3) grant. Funding covered macroinvertebrate sample processing, identification, metric calculations, data entry, and specimen verification for the second set of biological samples collected during the high flow period (April - June) in 1997. This grant was also used for a contract with Tetra Tech Inc. to compile the biological data, evaluate sample methodology, define bioregions, assess possible seasonal effects, establish core metrics, and develop a preliminary Tennessee Stream Condition Index (TSCI). This work was published in the report: *Evaluation of Tennessee Ecoregions: A Framework for Stream Classification and Bioassessment* (1998). In addition to this document, Tetra Tech Inc. developed a program in Microsoft Access called EDAS (Ecological Data Application System). It was developed to analyze macroinvertebrate data collected. Future development includes direct upload into EPA's national STORET database.

Data collected at reference streams will be used to define baseline conditions in least impacted streams in various regions across Tennessee. The ecoregion reference site framework will be used to enhance water quality criteria.

1.2 Project Goals and Objectives

1.20 Water Quality Criteria and Standards Development

The ecoregion/reference site framework will be used as a tool to implement the requirements of the Tennessee Water Quality Control Act. The Act requires the protection of state waters and their designated uses as defined by the Tennessee Water Quality Standards. These Standards consist of three parts. The first part defines designated uses. All waters have at least the basic four uses: fish and aquatic life, recreation, irrigation, and livestock watering and wildlife. The second part establishes the general water quality criteria needed to protect those uses. The third part is the antidegradation statement, which protects existing uses of all surface waters as established under the Act and strictly regulates authorization of degradation in high quality waters.

Various regions in Tennessee have distinct water quality and biotic characteristics. This makes it necessary to develop criteria specific to unique regions. The ecoregion framework provides a structure for the state to set water quality standards and criteria that vary with the natural background of the land. The framework describes water quality differences across the state. Streams and rivers reflect the land they drain thereby resulting in different water quality patterns. These patterns are affected by terrestrial characteristics such as bedrock, geology, soils, hydrology, wildlife, physiography, vegetation and precipitation. Level III Ecoregions cover thousands of square miles and contain large areas of naturally unique variability. In order to group biological, physical, and chemical characteristics of similar streams within the same geographic area, it is necessary to sub-regionalize the Level III ecoregions into smaller Level IV ecoregions (subregions). Tennessee's 25 subregions delineate areas of different terrestrial and water quality patterns.

In order to understand physical, chemical, and biological quality in subregions, it was necessary to establish reference sites. These sites were located on streams that were relatively undisturbed

and had minimal impact. They were also typical of other streams in the subregion they drained. Data collected from reference sites will be used in establishing attainable water quality standards and acceptable biocriteria. Reference data will also be used to facilitate watershed planning, compute waste load allocations, supplement total maximum daily loading calculations, locate monitoring and special study sites, and help identify management practices that would protect stream health and the adjacent terrestrial community.

1.21 Biocriteria Development

In order to assess biological integrity, biocriteria need to be developed. Biocriteria describe the optimal biological health of aquatic communities inhabiting waters designated for aquatic life use. Biological health is measured by community structure, species richness, abundance, trophic composition, tolerance to pollutants or other applicable indices. To establish values that are representative and attainable of actual background conditions, data must be collected from least impacted, minimally disturbed reference streams that are typical of a subregion. Therefore, reference sites needed to be identified and monitored to establish the baseline reference condition from which biological criteria could be developed.

EPA’s Region IV Biocriteria Program Support Document (EPA 1992b) provided guidance in establishing reference sites and sampling strategies to document representative aquatic communities (Table 1). Sound methods combined with multiple data points provide meaningful, protective, and scientifically defensible data to describe the expected health of biological communities in reference streams. Tennessee has accomplished steps 1 through 7 as outlined in this document. Development and application of biocriteria (steps 8 through 11) are currently underway.

Table 1 Biocriteria Implementation Guidelines EPA Region IV Biocriteria Program Support Document (1992b)	
1.	Select a regionalization scheme and refine ecoregions/subregions
2.	Select candidate unimpacted/relatively unimpacted reference watersheds
3.	Scout and select relatively unimpacted reference sites
4.	Choose biological communities, physical habitats and chemical parameters for sampling
5.	Document sampling protocols and QA/QC procedures
6.	Select an appropriate array of biological metrics for evaluation
7.	Sample reference sites to establish variability and statistical bounds for biological, physical habitat, and chemical parameters
8.	Develop scoring criteria for metrics (e.g., % comparability to reference)
9.	Establish condition categories for aquatic ecosystems based on severity of impairment
10.	Test applicability at a wide variety of impacted sites
11.	Adopt numerical biological criteria in state standards

1.22 The Ecoregion Framework and Watersheds

Watersheds drain ecoregions and subregions. Depending on size, many subwatersheds are contained within an ecological subregion. Comparisons can be made between watersheds, or parts of watersheds, that are contained within the same subregion. Large river systems tend to flow across several subregions and reflect a composite of the water quality characteristics of the subregions they drain. Subregions provide more uniform units of area to inventory, monitor, and assess surface waters than the commonly used USGS hydrologic unit frameworks alone.

EC066G05 Little River, upstream of Elkmont, GSMNP, Blount Co.

2. METHODS

2.1 Delineation Process

In 1986, James Omernik, NHEERL, delineated 76 Level III ecoregions in the contiguous United States on a map scale of 1:3,168,000. Each ecoregion was assigned a unique number. Portions of 8 ecoregions covered Tennessee. Due to the high diversity and complexity of these ecoregions, it was necessary to refine and subdivide the ecoregions into subregions. In 1994, WPC initiated an Ecoregion Delineation and Reference Site Selection Project in cooperation with the USEPA Region IV, and James Omernik and Glenn Griffith, NHEERL. The first step in the project was to refine Level III ecoregions and delineate Level IV ecoregions (subregions).

During the delineation process, small to medium scale (1:250,000 to 1:1,000,000) mapped information was gathered. These maps contained information on bedrock and surface geology, soil, hydrology, physiography, topography, precipitation, land use and vegetation. Interagency cooperation widened the base of maps, information, and resources available to delineate subregions. The USDA Natural Resources Conservation Service provided STATSGO maps based on county soil surveys. Draft maps of the US Forest Service's framework of ecological units were also utilized. The USGS EROS Data Center produced maps from composites of multi-temporal Advanced Very High-Resolution Radiometer (AVHRR) satellite data to assess physical boundaries and regional differences.

Water quality information from Tennessee's 1994 305(b) Report and reports developed by the Tennessee Valley Authority provided patterns of surface water quality. Much of this information was digitized to produce draft maps of ecoregion and subregion boundaries. The maps were revised after review in subsequent meetings with state, federal, and academic representatives. A more detailed description of the delineation process in Tennessee is found in the EPA document *Ecoregions of Tennessee* (EPA/600/R-97/022).

Multiple agencies were invited and represented at one of three ecoregion meetings held during 1994-1995. Attendees included aquatic biologists, ecologists, foresters, chemists, geographers, engineers, university professors, and regulatory personnel (Table 2). The judgment of these experts was applied throughout the selection, analysis, and classification of data to determine the final ecoregion and subregion boundaries in Tennessee.

2.2 Data Requirements

To describe the physical, chemical, and biological condition of subregion reference sites, it was necessary to define the type of data needed. Achieving this goal involved the following steps:

- Determine reference condition through intensive monitoring of regional reference streams.
- Determine a list of parameters and detection limits needed to make decisions on water quality.
- Develop Standard Operating Procedures (SOP) for field collections and sample analyses.
- Develop a Quality Assurance/Quality Control (QA/QC) strategy for sample collection and analyses.
- Train field personnel
- Collect a minimum of three years of data to determine seasonal influences and provide a sufficient statistical database
- Collect chemical samples quarterly and macroinvertebrate samples biannually.
- Centralize chemical and biological analyses to maximize consistent and efficient use of time, manpower and results.
- Review results to formulate general water quality, aquatic community structure, and habitat data ranges at reference sites.
- Summarize general findings.

It was anticipated that reference site monitoring would be long term and that changes in reference site selection, plus collection and sampling methodologies could occur over time.

2.3 Candidate Reference Site Identification

The next step in the ecoregion delineation process was the search for a set of reference streams. Mapped information, stream survey data, and shared field expertise were essential elements in locating candidate reference sites. In 1995, Glenn Griffith (NHEERL) compiled all available information to produce a statewide list of 231 potential reference sites.

The reference streams were chosen to represent the best attainable conditions for all streams with similar characteristics in a given subregion. Reference condition represents a set of expectations for physical habitat, general water quality, and the health of biological communities in the absence of human disturbance and pollution. Selection criteria for reference sites included minimal impairment and representativeness.

Activities that alter the natural landscape may also impact water quality. These activities may include land development, point source discharges, nonpoint source runoff, riparian destruction and erosion. Most of the reference streams had some degradation, but were less impacted than other streams in the same region. Representativeness meant reference sites had the same characteristics and conditions as the majority of streams in the subregion. Streams that did not flow across subregions were targeted so the unique characteristics of each subregion could be identified.

Site evaluation required field visits by experienced biologists to screen each candidate stream. A set of guidelines developed by Alabama and Mississippi (1994) were used as the basis for field reconnaissance. Potential sites were rated as to how well they met the following criteria:

- The entire watershed was contained within the subregion.
- The watershed was mostly or completely forested (if forest was the natural vegetation type) or has a typical land use for the subregion. The watershed may be contained within a National Forest, State Refuge or other protected area.
- The geologic structure and soil pattern was typical of the region.
- The watershed did not contain a municipality, mining area, permitted discharger or any other obvious potential sources of pollutants, including non-regulated sources.
- The watershed was not heavily impacted by nonpoint source pollution.
- The stream flowed in its natural channel and had not been recently channelized. There were no flow or water level modification structures such as dams, irrigation canals or field drains.
- No power or pipelines crossed upstream of the site.
- The watershed contained few roads.

Experienced field biologists conducted the initial site evaluations. Abbreviated screenings of the benthic community focusing on clean water indicator species were conducted at each potential site. Measurements of dissolved oxygen, pH, conductivity and water temperature were taken. Habitat assessments were also conducted. The

upstream watershed was investigated for potential impacts. Photographs were taken at most sites. Obviously impacted streams were dropped from consideration.

During field reconnaissance, an additional 122 sites were added to the original candidate list of 231 sites proposed for consideration. One hundred and thirty nine sites were dropped due to observable impacts during the initial field reconnaissance, therefore, 214 sites were left for consideration. The name and location of all sites under consideration can be found in Appendix A.

The original goal was to select three final reference sites per subregion. This was determined as the minimal number necessary to generate a statistically valid database. Three streams could not always be located in smaller subregions. A total of 70 candidate reference sites were selected by August 1996 for intensive monitoring.

2.4 Quality Assurance/Quality Control

The primary goal in data gathering was to maintain consistency, reliability, accuracy, and completeness of the data collected. All aspects of data acquisition, from field collection to laboratory processing and data analysis, were subject to QA/QC. This was accomplished through training, protocol guidelines, standard operating procedures, comprehensive field documentation, sample logging and duplicate sampling. Investigators with a scientific background and experience in field collection methods, stream ecology, and water quality performed all stream surveys. To ensure consistent, accurate, and reliable data collection and assessment, personnel performing stream survey work were trained in a uniform method. Training activities are outlined in Table 3.

Table 3. Field Training		
Workshop	Objective	Date
Habitat Assessment and Bioassessment	Develop a Tennessee SOP, update current protocols based on 1989 EPA RBP.	August 1994
Chemical Sampling	Develop a chemical sampling SOP based on a modified version of EPA Clean Techniques. Develop standard QA/QC procedures.	July 1996
Stream Habitat, Bioassessment and Metrics	Update habitat assessment protocols based on revised EPA RBP. Discuss Tennessee specific macroinvertebrate metrics.	March 1998

To achieve consistency throughout the project, it was necessary to update and compile existing regionalized bioassessment protocols into a unified standard operating procedure manual. This manual was an essential part of the QA/QC program because it documented methodologies for habitat assessments, stream characterization, macroinvertebrate collection, sample processing and data reduction.

In November 1994, a Habitat Assessment and Bioassessment workshop was conducted in Tennessee under the guidance of Michael Barbour, Tetra Tech Inc. Attendees were primarily Tennessee State biologists with representatives from federal agencies and adjacent states within EPA Region IV. By consensus, the major goal of the workshop was to obtain “*The most quality data for the least amount of effort*”. Participants addressed development of consistent habitat assessments, as well as fish and macroinvertebrate sampling protocols for Tennessee agencies that would be compatible with methods used by adjacent states. Technical issues included updating and refinement of current methods, defining reference conditions, collecting representative samples (standard field sampling methodologies), identifying source and cause (habitat impairment versus water quality), and accounting for seasonal effects.

The workshop laid the groundwork for a written set of Tennessee Standard Operating Procedures (TNSOP). The TNSOP was based on the 1989 EPA document: *Rapid Bioassessment Protocols for Use In Streams And Rivers - Benthic Macroinvertebrates And Fish* (Plafkin et al.). Minor changes to the Rapid Bioassessment Protocol III – Macroinvertebrates, resulted in a modified RBP III for Tennessee collections. The workgroup also reviewed and adopted habitat assessment forms designed by Barbour and Stribling (draft, 1994). The Tennessee Valley Authority (TVA) and Tennessee Wildlife Resources Agency (TWRA) modified the 1989 EPA fish protocols (RBP V) to more appropriately assess fish communities specific to Tennessee.

In 1995, the draft document *Tennessee Biological Standard Operating Procedures Manual: Volume I: Freshwater Aquatic Macroinvertebrates; Volume II: Fish Communities* (TNSOP) was released for review. It was finalized in 1996. In 1997, EPA released the draft EPA publication: *Revisions to Rapid Bioassessment Protocols for Use in Streams and Rivers: Periphyton, Benthic Macroinvertebrates, and Fish* (Barbour et al.). Portions of this updated manual were immediately adopted for use. The TNSOP was updated again in 1998 with adoption of Tennessee specific macroinvertebrate stream habitat and biometrics provided by a contractor (Tetra Tech Inc.). Field training was an ongoing process as sampling protocols were modified and updated. Training allowed immediate modification of field procedures as new protocols and EPA guidelines were adopted.

The 1996 Tennessee Standard Operating Procedures were followed for all macroinvertebrate collections during the ecoregion project. Bioassessment methods used by each team included habitat assessment, stream characterization, field measurements and single habitat semi-quantitative macroinvertebrate collections. All field parameters (dissolved oxygen, pH, conductivity and water temperature) were taken with calibrated Hydrolab or YSI meters. Calibration logs were kept on all meters. Minimally, ten percent of all readings were duplicated. Flow measurements were taken along transects with calibrated Marsh-McBearn flow meters.

To insure consistency in chemical collections, WPC developed a surface water sampling document titled *Standard Operating Procedure for Modified Clean Technique Sampling Protocol*. This document was based on EPA’s guidance document: *Method 1669: Sampling Ambient Water for Trace Metals at EPA Water Quality Criteria Levels and Appendix C: Guidance Concerning the Use of “Clean Techniques” and QA/QC when Measuring Trace Metals* (EPA821-R-95-034). Field training was conducted to ensure that all water quality

samples were collected in a uniform and consistent manner to minimize possible sample contamination. Two samplers were present during collections with only one handling the sample while the other filled out paperwork and handled equipment. Both samplers wore a new set of disposable gloves at each site. Sample bottles were double bagged, placed in clean coolers and delivered directly to the lab by the samplers. Ten percent of chemical collections had duplicate samples, field blanks and trip blanks taken.

Documentation was critical in the data gathering efforts. It provided the information needed to duplicate collection efforts to ensure reproducible results. Any unavoidable deviations from protocol were documented. Field forms and sample tags contained all necessary information. Field equipment maintenance and calibration was documented in logbooks to ensure that the results generated were accurate. Chain of custody was maintained on all chemical and biological samples.

Extensive quality assurance techniques were implemented during sample processing and reporting. All chemical and biological samples were processed at the state's laboratory to insure consistency. Unique log numbers were assigned to all samples for tracking purposes. A random ten percent of all biological samples were re-sorted and re-identified by a second taxonomist. At minimum, a 90% sorting efficiency and 95% identification accuracy was maintained by all taxonomists. Chemical and biological results underwent extensive data review, verification, and documentation. All data entries were verified.

Voucher collections containing representatives of all taxa found in that subregion were created for each of the 25 subregions. A master reference collection containing a representative of every taxa collected during the study was also created. All taxa in the master reference collection were sent to outside experts for verification. The voucher collections and master reference collection are maintained at the state laboratory. Partial reference collections were sent to each field office.

2.5 Habitat Assessment

2.50 Habitat Assessment Forms

Habitat assessments were conducted each time a site was sampled to document changes in habitat structure and availability over the three-year period. Good habitat quality is essential for a diverse macroinvertebrate assemblage. Degraded or altered habitat usually results in a stressed benthic community. Lack of good habitat can sometimes mask the effects of water quality problems such as toxicity or pollution.

Habitat assessment protocols developed by Barbour and Stribling (1994) were used at the beginning of the study. The protocols assessed riparian and in-stream habitat that could affect the structure of the macroinvertebrate community. This method assigned numeric values ranging from 1 to 20 for ten different habitat parameters. A total score of 200 was optimal. Two different forms were used depending on stream type (riffle/run or glide/pool).

In 1998, revised Habitat Assessment forms and protocols from the draft 1997 EPA manual were presented to state biologists in a bioassessment workshop. These were updates of the Barbour and Stribling forms (draft, 1994) designed to assess high gradient (riffle/run prevalent) and low gradient (glide/pool prevalent) streams. They were reviewed and adopted for immediate use. Habitat parameters and scoring criteria in the revised edition were compatible with the 1994 forms, so scores could be compared over time. Copies of the current habitat assessment forms, including scoring criteria, are located in Appendix C. Scoring criteria used in the habitat assessment evaluations are presented in Table 4.

Table 4: Habitat Assessment Parameters	
Riffle/Run (High Gradient)	Glide/Pool (Low Gradient) Streams
Epifaunal Substrate/Available Cover	Epifaunal Substrate/Available Cover
Embeddedness	Pool Substrate Characterization
Velocity/Depth Regime	Pool Variability
Sediment Deposition	Sediment Deposition
Channel Flow Status	Channel Flow Status
Channel Alteration	Channel Alteration
Frequency of Riffles (or Bends)	Channel Sinuosity
Bank Stability	Bank Stability
Vegetative Protection	Vegetative Protection
Riparian Vegetative Zone Width	Riparian Vegetative Zone Width

2.51 Stream Survey Form

A stream survey form (Appendix C) was also completed during each sampling event to provide additional information not documented in the habitat assessment. This form evolved over the course of the study (originally called Biological Data Sheet), but the essential information remained consistent. The form provided information on site location, physical/chemical parameters, watershed characteristics, sample point characteristics, physical stream characteristics, substrate type, sampling methods and included a stream sketch.

2.6 Macroinvertebrate Monitoring

2.60 Field Collections

Macroinvertebrate sampling at the reference sites began August 1996. Collection methods followed the 1996 TN SOP. Collections were planned to coincide with low flow (mid-August to mid-October) and high flow (mid-March to mid-May) periods to capture possible seasonal changes in the aquatic community. Six consecutive sampling events occurred over the first three years resulting in three late spring (high flow) and three late summer (low flow) collections by spring 1999. Subsequent monitoring will take place in conjunction with watershed monitoring.

Field teams from the Tennessee Department of Environment and Conservation (TDEC), and Tennessee Department of Health (TDH), participated in macroinvertebrate collections. All staff had experience and training in stream survey work including macroinvertebrate collection and identification methods.

The 1996 TNSOP macroinvertebrate sampling protocol followed a single habitat approach. Semi-quantitative samples were collected from the most productive habitat (either riffle or undercut bank). In streams containing riffle areas, two riffle kicks were collected using a 1 m², 500 micron mesh kick net. One 1m² kick was collected in fast moving water, and a second 1m² kick was collected from slower moving water flowing over a riffle. The two kicks were composited and preserved in the field. In non-riffle streams, semi-quantitative samples were collected with a 500 micron mesh A-framed dip net. Three 1 meter sweeps were collected from different areas of the stream banks, composited, and preserved in the field. All samples were sent to the state lab for sorting and identification.

Qualitative samples were collected in all available microhabitats during the first two sampling events. Collections made in each microhabitat were kept separate. Representative organisms were picked from the debris or substrate in the field. The taxa were preserved and sent to the state lab for identification. Qualitative collections were dropped after the first year (2 sampling episodes) in an effort to save field time and laboratory costs. Data were not used in metric development due to inconsistency in collecting techniques between field teams. Semi-quantitative sampling continued for an additional two years. A detailed description of the sampling protocol can be found in the 1996 TN SOP.

2.61 Laboratory Processing of Macroinvertebrate Samples

All macroinvertebrate samples were processed by experienced taxonomists at the central laboratory facility. Use of a centralized group ensured consistency, accuracy and efficiency in sorting, subsampling, identification, data entry and data reduction efforts. The late summer 1996 macroinvertebrate samples were subsampled by combining the entire sample in a 28 grid pan. Grids were selected until a minimum of 200 organisms were collected. If more than 200 organisms were found in the first grid, all individuals were counted. Samples collected after 1996 followed the subsampling protocol presented in the draft 1997 EPA manual. The sample was continuously subsampled in groups of 4 or more grids until a 200 (+/- 20%) sample was achieved. A ratio was taken on the 1996 data to make them comparable to a 200 organism subsample. Organisms were picked from the debris under a dissecting microscope by a taxonomist. Ten percent of all samples were re-sorted by a second taxonomist. All staff maintained a minimum 90% sorting efficiency.

Taxa were identified to the genus level by experienced taxonomists. Ten percent of all samples were re-identified by a second taxonomist. A 95% accuracy rate was maintained. Voucher collections containing representatives of all taxa found in that subregion were made for each of the 25 subregions. A master reference collection containing a representative of every taxa collected during the study was also created. All taxa in the master reference collection were sent

to outside experts for verification. Partial reference collections, containing regional taxa, were sent to each field office.

The first year of macroinvertebrate data (late Summer 1996 and late Spring 1997) were sent to Dr. Michael Barbour and Jeffrey White, Tetra Tech Inc. They provided a compilation of biological and habitat data, evaluated sampling methodology, recommended metrics for evaluating biota, and proposed index ranges based on gear type.

2.7 Water Quality Monitoring

In 1996, WPC developed a surface water sampling document, *Standard Operating Procedure for Modified Clean Technique Sampling Protocol*. This document was based on EPA's guidance document: *Method 1669: Sampling Ambient Water for Trace Metals at EPA Water Quality Criteria Levels* EPA821-R-95-034. Field staff in WPC, DOE-O, and TDH participated in a training workshop to ensure that equipment handling, field measurements, and surface water sampling techniques were consistent and accomplished with minimal contamination.

A parameter list was compiled at the initiation of the ecoregion project (Table 5). The list included ambient parameters that have been historically sampled. All parameters were collected at each reference site during the first season of sampling. To reduce costs, cyanide, mercury, sulfate, chloride and nickel were dropped when preliminary analyses showed little or no detection statewide for these parameters. Apparent color, true color, E. coli and enterococcus were added during the final year of the project. Low detection limits were selected to maximize the ability to quantify analytes.

Physical measurements and chemical and bacteriological sample collections began in the spring of 1996. Initially, water samples were collected quarterly for three consecutive days. This design was used to determine background consistency and repeatability of the sample collections provided field conditions remained unchanged. Since 1997, surface water samples were collected one day each quarter.

Chemical and bacteriological samples were collected in accordance with WPC's Standard Operating Procedure for Modified Clean Technique Sampling Protocol. Two trained field staff were present during all collections. Only one collector handled the sample (clean hands) while the other filled out paperwork and handled equipment (dirty hands) to reduce the possibility of cross contamination. Both samplers wore a new set of disposable gloves at each site. All sample bottles were double bagged, placed in clean coolers with ice and delivered directly to the lab by the samplers. Chain of custody was maintained at all times. Ten percent of all water quality collections had duplicate samples, field blanks and trip blanks taken.

Flow, dissolved oxygen, conductivity, pH and water temperature readings were measured in the field concurrent with chemical/bacteriological sampling. All readings were taken with calibrated meters. Calibration logs were maintained for each meter. Readings were taken midstream. At minimum, ten percent of all field readings were duplicated.

Chemical and bacteriological analyses was performed at the state laboratories in the Tennessee Department of Health Labs located in Jackson, Nashville and Knoxville Tennessee. All three labs were under central direction and followed EPA approved methodologies and quality assurance protocols.

3 RESULTS

The purpose of this section is to summarize data generated during the three-year study. Additional documents will contain more detailed analyses and interpretation, including data collected after the end of the study in 1999. Recommendations for regional biocriteria and refinement of water quality criteria may be presented in the next series of reports.

3.1 Level III and Level IV Tennessee Ecoregions

Twenty-five Level IV ecoregions were defined within the eight Level III ecoregions in Tennessee (Table 6). Some subregions contain unique benthic communities and water quality parameters. Preliminary analyses indicate some subregions are uniform enough to be combined, while others are unique enough to be kept distinct. The data generated from this study will be used to determine which regions can be combined for stream monitoring purposes. The data will establish expected biotic and water quality ranges for different regions. A more detailed description of the characteristics of each Level III and Level IV ecoregion can be found in Appendix A.

ECO69D01 No Business Branch, Hwy 25 near Morley, Campbell Co.

		74b Loess Plains	9.6%

3.2 Reference Sites

Changes in candidate reference sites occurred throughout the life of the project. Out of the original 70 sites selected for intensive monitoring, nine were dropped when intensive monitoring revealed impacts. Four subregions (65a, 65i, 67h, 67i) were dropped after initial monitoring due to their insignificant area in the state and/or the lack of unimpaired streams. Twenty-six sites were added either to replace dropped sites or to provide additional sites in larger or more diverse subregions. Since these streams were added after initiation of the project, three years of data are not available. The decision to drop or

add streams was done at the field office level. By the end of the project, there were 73 sites being monitored (Table 7). These sites, as well as any new streams that may be found, will continue to be monitored on a five-year rotation in conjunction with watershed monitoring. A list of all candidate and final reference sites is provided in Appendix B.

Ecological Subregion	# Stations Fall 96	# Stations May 99	Stations Changed
65a	2	0	2 dropped
65b	2	1	1 dropped
65e	3	5	2 added
65i	2	0	2 dropped
65j	3	4	1 added
66d	2	3	1 added
66e	3	3	No change

73a	1	3	3 added, 1 dropped
74a	2	3	1 added
74b	3	3	No change

3.3 Statistical Design:

Box plots were used to evaluate habitat, biological and water quality variations between reference sites and ecoregions. A box plot is a graph that displays the 10th, 25th, 50th, 75th and 90th percentiles of a variable. The plot is composed of a central box divided by a line, and two lines extending out from the box called whiskers. The box contains the middle half of the scores in the distribution. The length of the box indicates the distribution of the middle 50% of the data. The lower and upper hinges of the box mark the 25th and 75th quartiles of the data respectively.

The line through the box represents the sample median. Boxes in which the median does not fall near the middle of the box represent skewed data. The whiskers represent the 10th and 90th percentiles. Whisker length corresponds to the spread of the data. Outliers are points that fall outside of the 90th (10th) percentile. Outliers are a common occurrence in environmental data.

Box plots are useful because they allow direct side-by-side comparison of data from several groups within a single figure. Each box plot graphically illustrates the central tendency (median; center of the data), variability (interquartile range; spread of the middle 50% of the data), minimum and maximum values (the full range) of a data set as a single icon (picture). The relationship between the data sets is shown by the amount of overlap of the median and interquartile between boxplots. When the median and interquartile ranges overlap, the data sets are very similar. When the median and interquartile ranges do not overlap, the data sets are very different. For summarization purposes in this report, data groups were determined to be statistically different when the median and interquartile ranges did not overlap. More rigorous statistics will be used to determine significant difference during metric development in subsequent documents.

3.4 Habitat Assessment

Habitat scores varied significantly between Level III ecoregions (Table 8 and Figure 2). As expected, streams in the Blue Ridge Mountains (66) generally had higher scores than other regions. Many of the reference streams in this region have protected watersheds.

The most western of the Tennessee ecoregions encompassing the Mississippi Alluvial Plains (73) and the Mississippi Valley Loess Plains (74) had the lowest scores. Most of the streams in these regions are low gradient with sandy bottoms. Large areas of cropland dominate both regions. Stream channelization and riparian loss combined with erosion are prevalent in most watersheds in these two regions. Although reference streams were selected for least impairment, all were impacted to some extent.

There were also differences in habitat availability at the subregional level (Level IV) in many ecoregions. Within the Southeastern Plains (65), the Transition Hills (65j) had consistently high scores (Figure 3). The higher gradient cobble-bottom streams in this area are atypical of the rest of the ecoregion. On the other hand, the Blackland Prairie (65a) covers a very small area in Tennessee. Only a few streams are found in this region. This narrowed the reference stream possibilities, which required the selection of relatively impaired streams. This resulted in lower habitat scores in this subregion than in the surrounding regions. Habitat scores from 65a reference sites will be compared to data from other states that have larger areas in 65a to determine if values are typical. If scores are atypical, subregion 65a will be evaluated at the larger ecoregion level.

Within the Blue Ridge Mountains Region (66), the Southern Igneous Ridges and Mountains (66d) had the highest and most consistent habitat scores (Figure 4). As expected, the most variability and lowest scores in this ecoregion were observed in the

Limestone Valleys and Coves (66f). This subregion is the most developed within the Blue Ridge Mountains.

The Southern Shale Valleys (67g) of the Ridges and Valleys ecoregion had low habitat scores compared to the Southern Limestone/Dolomite Valleys and Low Rolling Hills (67f) and the Southern Sandstone Ridges (67h). This would be expected, since land use in the southern shale valleys is heavily agriculture. Due to the lack of suitable streams, only two streams, both of marginal reference quality, were targeted for monitoring. The Southern Dissected Ridges and Knobs (67i) had the lowest overall scores in the subregion (Figure 5). It is generally atypical for wooded ridges to have lower scores than more developed valley areas. The data for these subregions may be misleading since it is based on only 2 reference streams, with one having significantly lower habitat quality. The low scoring parameters were embeddedness, sediment deposition and riparian width.

Within the Southwestern Appalachians (68), streams in the Cumberland Plateau (68a) had the highest habitat quality (Figure 6). The heavily developed Sequatchie Valley (68b) had relatively low habitat scores with a mean value of 142. The Plateau Escarpment (68c) fell between these two subregions.

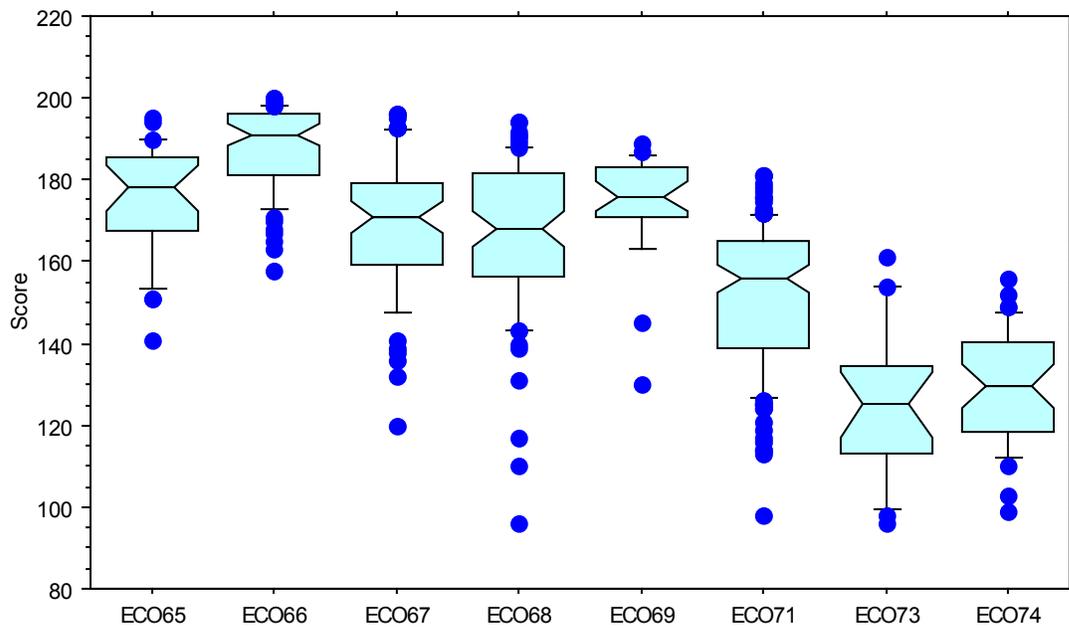

A marked difference was seen between subregional habitat scores in the Interior Plateau (71). The Inner Nashville Basin (71i) had significantly lower scores than other subregions in the Interior Plateau (Figure 7). Streams in this region naturally have poor habitat due to bedrock substrate and extreme seasonal flow variation. There is much urban development in this region, which makes selection of unimpaired streams difficult.

Although they contain different stream types, habitat scores between the Bluff Hills (74a) and the Loess Plains (74b) in the Mississippi Valley Loess Plains were comparable (figure 8). The Bluff Hills streams are gravel bottom riffle streams with a relatively high gradient. Riffle/Run parameters were used to assess the habitat quality. The Loess Plains are lower gradient streams that were assessed using glide/pool parameters. Both subregions have a great deal of human impact as reflected in the low habitat scores. The biggest problems are sedimentation and loss of riparian. The habitat scores for each station are presented in Appendix D.

Table 8: Habitat Assessments by Subregion

Subregion	Habitat Type	No. of Stations	No. of Observations	Score range	Mean Score
65a	Glide/Pool	2	7	71-151	88
65b	Glide/Pool	2	9	108-162	126
65e	Glide/Pool	6	34	123-181	150
65i	Glide/Pool	3	9	108-154	130

3.5 Macroinvertebrate Analyses

Biometrics were used to evaluate the macroinvertebrate community at each site. Biometrics measure the characteristics of the biota that change in some predictable way with increased human influence. For a metric to be useful, it must be ecologically relevant to the biological assemblage and to program objectives. It must also be sensitive to stressors and provide a response that can be discriminated from natural variation.

The first year of macroinvertebrate data was analyzed by Dr. Michael Barbour and Jeffery White, Tetra Tech Inc. to develop a core set of metrics that would best fit Tennessee macroinvertebrate community assessments. Seven metrics from four different category types (richness, composition, tolerance and habit) were used to reflect various aspects of the whole community. Richness metrics measure the diversity or variety of the macroinvertebrate community. Composition metrics measure species identity and dominance. Tolerance metrics measure sensitivity to pollution. Habit (trophic) metrics provide information on feeding strategies or guilds.

Use of multiple metrics is the most comprehensive method to assess the health of the benthic community. Use of a single metric can be misleading since different metrics respond differently to various stressors. For example the % of EPT, which is generally considered an indication of a healthy stream, may be high due to the presence of one or two nutrient tolerant taxa such as *Stenonema* spp. or *Cheumatopsyche* spp. However, the dominance of these two EPT groups would result in a low EPT richness and a higher NCBI indicating a stressed macroinvertebrate community.

Barbour and White (98) combined the proposed core metrics into a preliminary stream condition index based on stream type. The Tennessee Stream Condition Index (TSCI) was used to compare subregions. Each of the seven metrics is given a score of 0 to 6 based on the ranges in Table 10. The 7 scores are added for a total possible score of 42. The maximum index score range was quadrisected by Barbour and White (98) into equal ordinal categories of:

“Very Good”	32-42
“Good”	22-30
“Poor”	12-20
“Very Poor”	0-10

The preliminary core metrics proposed by Tetra Tech were adopted in 1997 and were used to analyze the benthic data from the entire three-year period (Table 11). Biometrics used during the three-year project are listed in Table 9. These metrics, as well as others, will be evaluated in subsequent documents to determine which are the most sensitive to disturbances in the benthic community.

Table. 9 Tennessee Preliminary Macroinvertebrate Metrics*			
Category	Metric	Definition	Expected response to increasing perturbation
Richness Metrics	Number of taxa	Measures the overall variety of the macroinvertebrate assemblage	Number Decreases
	Number of EPT taxa	Number of taxa in the insect orders Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies)	Number Decreases
Composition Metrics	% EPT	% of Ephemeroptera, Plecoptera, and Trichoptera	Percent Decreases
	% Chironomidae**	% Chironomidae taxa	Percent Increases
Tolerance/Intolerance Metrics	% Tolerant organisms	% of all organisms considered to be very tolerant to perturbation	Percent Increases
	NCBI	The North Carolina Biotic Index, which incorporates richness and abundance with a numerical rating of tolerance	Number increases
Habit Metric	% Clingers	% of organisms having fixed retreats or adaptations for attachment to surfaces in fast-moving water	Number Decreases

* Table modified from Kerans and Karr (1994) in Barbour and White (1998) to illustrate Tennessee preliminary metrics only.

Barbour's preliminary index created scoring ranges based on stream type, regardless of ecoregion. One problem associated with using ranges based only on stream type (riffle run or glide pool) is that riffle streams in mountainous areas are compared to riffle streams in valley areas. This results in very broad metric ranges. Based on subsequent data analyses, several subregions appear to have unique benthic characteristics. An eventual goal of this study is to develop expected ranges for each of the eight level III ecoregions as well as any unique subregions.

The preliminary TSCI did not appear sensitive to differences between all level III ecoregions. Benthic communities would be expected to be different at this level. The index indicated that ecoregions 67 (Ridge and Valley), 68 (Southwestern Appalachian), and 71 (Interior Plateau) had similar benthic communities (Figure 9). Before it is determined that these ecoregions are similar, it will be necessary to look closer at metric selection and range determination. The use of a combined index will also be evaluated since it tends to be less sensitive than looking at individual metrics.

Box and whisker plots of TSCI scores for each ecoregion that contains multiple subregions is presented in Figures 10–15. Review of these plots indicate that at least 6 subregions have distinctly different macroinvertebrate communities from other subregions within the same Level III ecoregion. The unique subregions are 65i (Fall Line Hills), 65j (Transition Hills), 67g (Southern Shale Valleys), 68a (Cumberland Plateau), 71i (Inner Nashville Basin) and 74b (Bluff Hills). These subregions will probably warrant different index ranges to determine macroinvertebrate community health.

Using the preliminary TSCI, streams in three subregions, 65i (Fall Line Hills), 73a (Northern Mississippi Alluvial Plain) and 74a (Bluff Hills) fell in the third quartile, which is considered poor (Table 11). Further analysis, as well as comparisons to reference streams in other states, is necessary to determine whether the streams selected in these regions are the best attainable or if they are too impacted for use as reference streams. If they are found to be useable, metric ranges will need to be adjusted in these regions. A table of scores for each station can be found in Appendix E.

3.6 Seasonal Variation

Most subregions were not collected within a sufficient time period to determine possible seasonal variations. Although different taxa would be expected in different seasons, the stream condition index may not vary significantly since the overall community structure could remain stable. It would be preferable to have a single expected range for each metric that could be used year round.

In order to determine if there is seasonal variation, it would be necessary to collect samples in tighter windows (6 weeks) within subregions. Ten of the 25 subregions were collected within 6 week (42 day windows) for both summer and spring samples. These subregions are highlighted in Table 12. They are primarily in the smaller subregions. Of the ten subregions sampled within seasonal windows, five showed an observable variation in TSCI scores between the summer and spring sample periods (Figures 16-25).

Table 12: Macroinvertebrate Samples by Season, TN Ecoregion Project, 1996-99

3.7 Water Quality Analyses

As with habitat and macroinvertebrate data, many water quality parameters were statistically different between the eight Level III ecoregions. For example, Figure 26 illustrates that the dissolved residue levels were highest in ecoregions 67 (Ridge and Valley), 71 (Interior Plateau), 73 (Mississippi Alluvial Plain) and 74 (Mississippi Valley Loess Plains). Nitrate and nitrite levels were also highest in ecoregions 67 and 71, while 73 and 74 were in line with the other ecoregions (Figure 27). Of the metals, copper was the most variable between ecoregions (Figure 28).

Some water quality parameters were different between level IV subregions while others were not. Within the five subregions of the Interior Plateau (71), combined nitrate and nitrite levels varied considerably (Figure 29). The Western Pennyroyal Karst subregion (71e) had the highest levels while the Western Highland Rim (71f) had the lowest. Other parameters, such as copper, were consistent between subregions in the Interior Plateau (Figure 30).

3.8 Relationship of Results to Water Quality Standards

National criteria for toxic substances are developed by EPA to identify levels of substances that are generally non-toxic to a wide range of test organisms. Criteria are based on specific toxicity testing results, but also contain “uncertainty factors” designed to compensate for unknown factors such as synergistic effects. Criteria are normally established at both acute and chronic levels.

States are encouraged by EPA to establish criteria at the national criteria levels, but are free to set criteria at more conservative levels, if desired. States may also set criteria at less conservative levels, but must provide an acceptable scientific justification. For those substances included in our study of reference streams, Tennessee has criteria established at the national criteria level, where available.

Prior to initiation of the ecoregion reference stream sampling, it was commonly theorized by people in the regulated community that even at true background levels, chemical substances routinely violated numerical criteria for protection of fish and aquatic life. This view was often presented as support for the notion that water quality standards were set inappropriately low.

Reference stream sampling results appear to refute this theory. Some substances were rarely detected, even when analytical methods that ensured very low detection levels were used. One of the most significant findings of this study is that the majority of chemical substances never exceeded water quality standards at any reference stream.

Additional information about the relationship between chemical and bacteriological results and water quality standards is presented in Table 13. For those substances where toxicity is a function of hardness, appropriate adjustments have been made.

Table 13: Relationship Between Concentrations of Various Substances and Water Quality Standards*		
Occurrence	Substance(s)	Comments
Substances never or rarely detected in reference stream sampling.	Cyanide Mercury Nickel Cadmium Ammonia	Cyanide, mercury, and nickel were dropped from reference stream sampling after the first year due to the absence of detections and the need to reduce analytical costs.
Substances occasionally detected in reference stream sampling.	Total chromium	The most toxic form is hexavalent chromium. However, total chromium was generally at undetectable levels
Substances regularly detected in reference stream sampling, but at levels less than applicable standards.	Copper Arsenic Lead Zinc	These substances were more commonly detected, but only lead levels in low hardness systems ever approached criteria levels. (EPA is in the process of revising the arsenic criteria for drinking water.) Zinc was detected in some of the “blank” samples used for quality control purposes.
Substances that occasionally violated applicable water quality standards.	Fecal coliforms <i>E. coli</i> Dissolved oxygen pH	The applicable water quality standards for pathogens are those established for protection of recreational uses. See text below for more discussion.

At the time of writing, numeric fish and aquatic life standards are not available for the following substances: conductivity, turbidity, nutrients, color, iron, manganese, suspended or dissolved solids.

Pathogens - While metals concentrations rarely approached criteria levels, a different pattern was documented for pathogens. Almost all reference sites indicated spikes in bacterial concentrations, especially during high flows. Some of these spikes exceeded water quality standards for pathogen levels in an instantaneous sample. However, no station had geometric mean levels that exceeded water quality standards.

Dissolved Oxygen - In ecoregion 73 (Mississippi Alluvial Plain), the average dissolved oxygen level in reference streams was 4.1 mg/L, less than the 5 mg/L water quality standard for fish and aquatic life protection. In all other ecoregions, average oxygen levels were higher than 5.0 mg/L. However, in several subcoregions, dissolved oxygen levels occasionally violated the water quality standard, especially during low flow

conditions. These violations were especially obvious in ecoregion 74 (Mississippi Valley Loess Plains) and in subcoregion 71i (Inner Nashville Basin).

pH - In all ecoregions, the average pH readings were within the range of 6.5 to 9.0 established as Tennessee's water quality standard for fish and aquatic life protection. (The authors are aware that it is not entirely proper to average pH levels). However, in almost every subcoregion, pH levels occasionally to regularly fell below 6.5, especially in subcoregions 68a (Cumberland Plateau) and 69d (Cumberland Mountains), and in west Tennessee. In west Tennessee, these are generally considered to reflect natural pH fluctuations, including the influence of groundwater. Along the Cumberland Plateau and Cumberland Mountains, the possible influence of historical mining activities cannot be ruled out.

Temperature - Temperature values did not exceed the 30.5°C standard at any reference stream. However, one observation in a stream in subcoregion 71i (Inner Nashville Basin) equaled the standard. 71i streams commonly have flat bedrock substrates and reduced flows. It is not uncommon for summertime water temperatures to be elevated in these streams.

Tables 14 through 21 present summary statistics for chemical, physical and bacteriological data for each Level III ecoregion. Raw water quality data are presented in Appendix F. (Due to publication considerations, not all copies of this report contain Appendix F. STORET data may be obtained through EPA's webpage.)

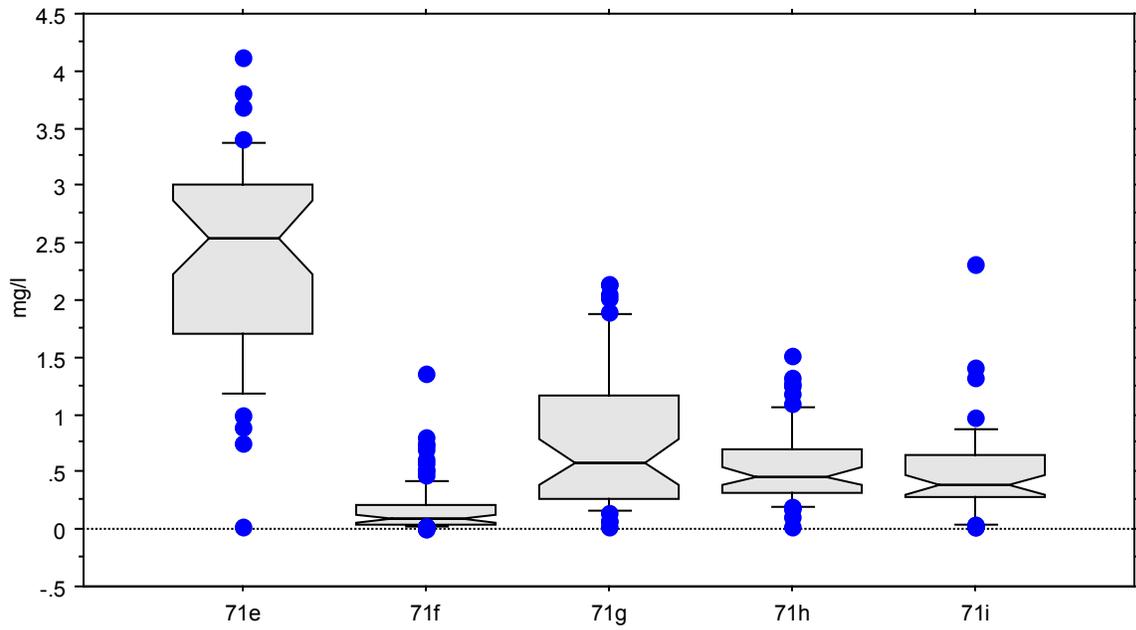

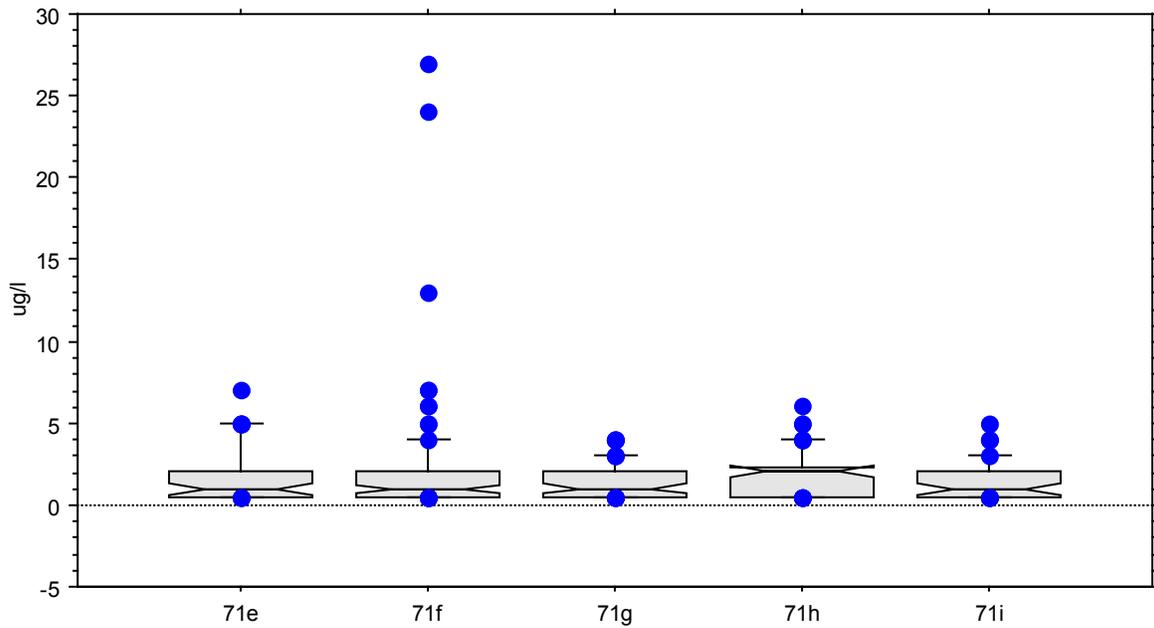

Figure 30: Copper Levels for Ecoregion 71, April 1996 - November 1999, Tennessee

4 CONCLUSIONS

Tennessee's eight Level III ecoregions have been delineated into 25 level IV subregions. Preliminary analyses of reference streams indicate that all eight ecoregions and at least six subregions have unique macroinvertebrate populations. The six subregions that appear to have distinct macroinvertebrate communities are 65i (Fall Line Hills), 65j (Transition Hills), 67g (Southern Shale Valleys), 68a (Cumberland Plateau), 71i (Inner Nashville Basin) and 74b (Bluff Hills). These subregions will probably warrant different stream condition index ranges to determine macroinvertebrate community health. Other regions appear to have similar macroinvertebrate communities and can probably be combined for assessment purposes.

Using the preliminary TSCI, three subregions, 65i (Fall Line Hills), 73a (Northern Mississippi Alluvial Plain) and 74a (Bluff Hills) fell in the third quartile (poor category). Further analysis as well as comparisons to reference streams in other states is necessary to determine whether the streams selected in these regions are the best attainable in the subregion.

Habitat assessment scores varied between many subregions. Variations were sometimes due to a lack of suitable reference quality streams, especially in the smaller subregions. Good habitat is critical to a healthy macroinvertebrate community. Habitat alteration is clearly an important reason for loss of use support in streams. Currently, Tennessee does not have a narrative or numeric criteria that establishes a goal for habitat quality. However, habitat alteration is specifically mentioned in the narrative criteria for biological integrity.

The results of the reference stream sampling indicate that the reasonable expectation for habitat scores should vary across the state. Thus, ecoregion or subregion specific criteria would be more accurate and meaningful than a statewide criteria. The data collected at the reference streams could be used to create such criteria. One potential impediment to acceptance of such a criteria would be the perception that habitat scoring is more subjective than other types of chemical or biological analyses.

Most subregions were not collected in close enough windows to determine whether there was significant seasonal variation. Although different macroinvertebrate taxa would be expected in different seasons, the stream condition index may not vary significantly since the overall community structure would remain stable. A single expected range for each metric that could be used year round would be preferable. In order to determine if there is seasonal variation, additional samples in a tighter time of collection (6 weeks) within each subregions would be necessary. Ten of the 25 subregions were collected within 6 week (42 day windows) for both summer and spring samples. They are primarily in the smaller subregions. Of the ten subregions sampled within seasonal windows, five of them showed a possibly significant difference in TSCI scores between the summer and spring sample periods. If seasonal ranges are not refined, a single broad index scale will be used to evaluate both spring and summer macroinvertebrate assemblages.

As with habitat and macroinvertebrate data, many water quality parameters varied between Level III ecoregions. For example, dissolved residue levels were highest in ecoregions 67 (Ridge and Valley), 71 (Interior Plateau), 73 (Mississippi Alluvial Plain) and 74 (Mississippi Valley Loess Plains). Nitrate and nitrite levels were also highest in ecoregions 67 and 71, while 73 and 74 were comparable to the other ecoregions. Of the metals, copper was the most variable between ecoregions.

Some water quality parameters were significantly different between Level IV subregions while others were not. Within the five subregions of the Interior Plateau (71), combined nitrate and nitrite levels varied significantly. The Western Pennyroyal Karst subregion (71e) had the highest levels while the Western Highland Rim (71f) had the lowest. Other parameters, such as copper, were consistent between subregions in the Interior Plateau.

The results of the reference stream sampling do not provide a rationale for the consideration of ecoregion specific criteria for the following substances since there was little or no variation between subregions:

Lead	Manganese	Arsenic
Copper	Iron	Cadmium
Chromium	Zinc	Ammonia

For multiple additional substances, while there is little justification to consider ecoregion-specific criteria revisions at this time, the Division should consider the patterns of violations of water quality standards at reference streams while assessing use support in other similar streams within the same subcoregions. (The reader should note that this ability to use judgement in considering the “magnitude and duration” of water quality violations is specifically given to the Division in Chapter 1200-4-3.05.) These substances are:

Dissolved oxygen	Fecal coliform	pH
Temperature	<i>E. coli</i>	

Reference stream data could and perhaps should be used to create regional interpretations for the following substances for which Tennessee currently only has narrative criteria:

Nitrate+Nitrite	Total nitrogen	Suspended residue
Total phosphorus	Turbidity	True color

Additional analysis will be necessary before specific criteria recommendations are possible. This work will be the subject of future reports.

5 Future Goals

The purpose of this report was to summarize data generated during the three year ecoregion delineation and reference stream selection study. A series of additional documents will be produced which will contain more detailed analyses and interpretation, especially for those substances for which the Division will propose ecoregion specific water quality criteria. These documents will also include data collected at reference sites after the end of the three year study in 1999.

The next phase of macroinvertebrate analyses will be to develop numeric biocriteria for unique subregions and will be presented in the next report. The objectives will be to:

1. Compare individual stations within subregions both by macroinvertebrate and chemical composition to determine if they are reference quality.
2. Determine which subregions need additional or better quality streams to have enough data for biocriteria determination.
3. Compare subregions to determine which ones have unique macroinvertebrate communities.
4. Review preliminary core metrics to determine if they are the most sensitive to differences in the macroinvertebrate communities across the state.
5. Determine appropriate metric scores for each subregion.
6. Calibrate reference metrics by comparison to impaired streams in each subregion.

Habitat scores also varied significantly between many subregions. Currently, Tennessee does not have a narrative or numeric criteria that establishes a goal for habitat quality. Since good habitat is critical to the macroinvertebrate community, the Division will also consider development of habitat goals.

The results of the reference stream sampling indicate that the reasonable expectation for habitat scores should vary across the state. Thus, ecoregion or subregion specific criteria would be more accurate and meaningful than a statewide criteria. The data collected at the reference streams could be used to create such criteria. One potential impediment to acceptance of such a criteria would be the perception that habitat scoring is more subjective than other types of chemical or biological analyses.

APPENDIX A

Physical Characteristics of Level III and Level IV Ecoregions in Tennessee

Adapted from Griffith et al. 1997 Ecoregions of Tennessee EPA/600/R-97/022

LEVEL III ECOREGIONS

Ecoregion 65. Southeastern Plains

These irregular plains are a mosaic of cropland, pasture, woodland, and oak-hickory-pine forest. The Cretaceous or Tertiary -age sands, silts and clays of the region contrast geologically with the older limestone, chert, and shale found in the Interior Plateau (71). Elevations and relief are greater than the loess plains of Ecoregion 74 to the west, but generally less than the Interior Plateau (71) to the east. Streams in this area are relatively low-gradient and sandy-bottomed.

Ecoregion 66 Blue Ridge Mountains

The Blue Ridge Mountains of Tennessee are characterized by forested slopes, and cool, clear high gradient streams. The rugged terrain is a mix of igneous, metamorphic, and sedimentary geology. Annual precipitation of nearly 80 inches can occur on the well - exposed high peaks of the Great Smoky Mountains that reach over 6000 feet. The southern Blue Ridge is one of the richest centers of biodiversity in the eastern U.S. It is the most floristically diverse ecoregion of the state, and includes Appalachian oak forests, northern hardwoods, and Southeastern spruce-fir forests. Shrub, grass, and heath balds, hemlock, cove hardwoods, and oak-pine communities are also significant.

Ecoregion 67 Ridge and Valley

Also known as the Great Valley of East Tennessee, this is a relatively low-lying region between the Blue Ridge Mountains to the east and the Cumberland Plateau on the west. As a result of extreme folding and faulting events, the roughly parallel ridges and valleys come in a variety of widths and heights. Geologic materials include limestone, dolomite, shale, siltstone, sandstone, chert, mudstone, and marble. Springs and caves are relatively numerous. Present-day forests cover about 50% of the region. The ecoregion has great aquatic habitat diversity in Tennessee and supports a diverse fish fauna rivaled only by that of the Highland Rim.

Ecoregion 68 Southwestern Appalachians

Stretching from Kentucky to Alabama, these open low mountains contain a mosaic of forest and woodland with some cropland and pasture. The eastern boundary of the ecoregion in Tennessee, along the more abrupt escarpment where it meets the Ridge and Valley (67), is relatively smooth and only slightly notched by small eastward flowing stream drainages. The western boundary, next to the Interior Plateau's Eastern Highland Rim (71g), is more crenulated with a rougher escarpment that is more deeply incised. The mixed mesophytic forest is restricted mostly to the deeper ravines and escarpment slopes. The upland forests are dominated by mixed oaks and short leaf pine.

Ecoregion 69 Central Appalachians

The Central Appalachian ecoregion, stretching from northern Tennessee to central Pennsylvania, is primarily a high dissected plateau composed of sandstone, shale, conglomerate, and coal. The rugged terrain, cool climate, and infertile soils limit agriculture resulting in a mostly forested landcover. The high hills and low mountains are covered by a mixed mesophytic forest with areas of Appalachian oak and northern hardwoods. Bituminous coal mines are common, and have caused siltation and acidification of streams.

Ecoregion 71 Interior Plateau

The Interior Plateau is a diverse ecoregion extending from southern Indiana and Ohio to northern Alabama. Rock types are distinctly different from the coastal plain sands of western Tennessee ecoregions, and elevations are lower than the Appalachian ecoregions to the east. Mississippian to Ordovician-age limestone, chert, sandstone, siltstone and shale compose the landforms of open hills, irregular plains, and tablelands. The natural vegetation is primarily oak-hickory forest, with some areas of bluestem prairie and cedar glades. The region has the most diverse fish fauna in Tennessee.

Ecoregion 73 Mississippi Alluvial Plain

This riverine ecoregion extends from southern Illinois, at the confluence of the Ohio and Mississippi River, south to the Gulf of Mexico. It is mostly a flat, broad floodplain with river terraces and levees providing the main elements of relief. Regionally, the soils tend to be poorly drained, although locally, some sandy soils have good drainage. Winters are mild and summers are hot, with temperatures and precipitation increasing from north to south. Bottomland deciduous forest vegetation covered the region before clearance for cultivation.

Ecoregion 74 Mississippi Valley Loess Plains

This ecoregion stretches from near the Ohio River in western Kentucky to Louisiana. It consists primarily of irregular plains, with oak-hickory and oak-hickory-pine natural vegetation. Thick loess tends to be the distinguishing characteristic. With flatter topography than the Southeastern plains (65) to the east, streams tend to have less gradient and more silty substrates. In Tennessee, row crops are the dominant land use.

LEVEL IV ECOREGIONS

65a The **Blackland Prairie**, extending north from Mississippi, is a flat to undulating lowland region entirely within a small portion of McNairy County, Tennessee. Although there is some of the Cretaceous-age chalk, marl, and calcareous clay that characterizes the region in Mississippi and Alabama, the northern extent of the Blackland Prairie in Tennessee is not distinct. The natural vegetation was sweetgum, post oak, and red cedar, along with patches of bluestem prairie. Today, the area is mostly in cropland and pasture, with small patches of mixed hardwoods.

65b The **Flatwoods/Alluvial Prairie Margins** extend north from Mississippi, but the distinctiveness of this narrow ecoregion belt fades quickly from Ripley, Mississippi north into Tennessee. In Mississippi and Alabama, this is a transition region between the Blackland Prairie and the more forested plains and hills. Some areas are heavily forested, but the prairie and alluvial areas have significant amounts of cropland and pasture. In Tennessee, the small region stands out as lower, less hilly agricultural land compared to the forested Southeastern Plains and Hills (65e) that surround it.

65e The **Southeastern Plains and Hills** contain several north-south bands of sand and clay formations. Tertiary sand, clay, and lignite are to the west, and Cretaceous fine sand, fossiliferous micaceous sand, and silty clays are to the east. With elevations reaching over 650 feet, and more rolling topography and more relief than the Loess Plains (74b) to the west, streams have increased gradient, generally sandy substrates, and distinctive faunal characteristics for west Tennessee. The natural vegetation is oak-hickory, grading into oak-hickory-pine to the south.

65i **The Fall Line Hills** ecoregion, comprising the Tennessee or Tombigbee Hills in Mississippi and the Fall Line Hills in Alabama, is composed primarily of Cretaceous coastal plain sandy sediments. The sand and chert gravel surficial materials are covered by sandy loam topsoils. It is mostly forested terrain of oak-hickory-pine on open hills with 100-200 feet of relief. Elevations in the small Tennessee portion, roughly between Chambers Creek and Pickwick Lake in Hardin County, are 450-685 feet.

65j **The Transition Hills** have the highest elevations in Ecoregion 65, and contain characteristics of both the Southeastern Plains (65e) and the Interior Plateau (71). Many streams of this transition area have cut down into the Mississippian, Devonian, and Silurian-age rocks and may look similar to those of the Interior Plateau (71). Cretaceous-age coastal plain deposits of silt, sand, clay, and gravel overlie the older limestone, shale, and chert. It is a mostly forested region of oak-hickory-pine with pine plantations associated with pulp and paper operations.

66d **The Southern Igneous Ridges and Mountains** occur in Tennessee's northeastern Blue Ridge near the North Carolina border, primarily on Precambrian igneous, gneiss, schist, and metavolcanics, covered by well-drained, acidic brown loamy soils. Elevations of this rough, dissected region range from 2000-6200 feet, with Roan Mountain reaching 6286 feet. Although there are a few small areas of pasture and apple orchards, the region is mostly forested. Appalachian oak and northern hardwoods forests predominate.

66e The **Southern Sedimentary Ridges** in Tennessee include some of the westernmost foothill areas of the Blue Ridge Mountains ecoregion, such as Bean, Starr, Chilhowee, English, Stone, Bald, and Iron Mountain. Slopes are steep with elevations of 1000-4500 feet. The rocks are primarily Cambrian-age sedimentary (shale, sandstone, siltstone, quartzite, conglomerate), although some lower stream reaches occur on limestone. Soils are predominantly friable loams and fine sandy loams with variable amounts of sandstone rock fragments. Natural vegetation is mostly mixed oak and oak-pine forests.

66f **Limestone Valleys and Coves** are small but distinct lowland areas of the Blue Ridge, with elevations mostly between 1500 and 2500 feet. About 450 million years ago, older Blue Ridge rocks to the east were forced up and over younger rocks to the west. In places, the Precambrian rocks have eroded through to Cambrian or Ordovician-age limestones, as seen especially in isolated, deep cove areas that are surrounded by steep mountains. The main areas of limestone include the Mountain City lowland area and Shady Valley in the north; and Wear Cove, Tuckaleechee Cove, and Cades Cove of the Great Smoky Mountains in the south. Hay and pasture, with some tobacco patches on small farms, are typical land uses.

66g The **Southern Metasedimentary Mountains** are steep, dissected, biologically-diverse mountains that include Clingmans Dome (6643 feet), the highest point in Tennessee. The Precambrian-age metamorphic and sedimentary geologic materials are generally older and more metamorphosed than the Southern Sedimentary Ridges (66e) to the west and north. The Appalachian oak forests and, at higher elevation, the northern hardwoods include a variety of oaks and pines, as well as silverbell, hemlock, yellow poplar, basswood, buckeye, yellow birch, and beech. The native spruce-fir forest, found generally above 5500 feet, has been affected greatly over the past twenty-five years by the great woolly aphid. The Copper Basin, in the southeast corner of Tennessee, was the site of copper mining and smelting from the 1850's to 1987, and once left more than fifty square miles of eroded bare earth.

67f The **Southern Limestone/Dolomite Valleys and Low Rolling Hills** form a heterogeneous region composed predominantly of limestone and cherty dolomite. Landforms are mostly low rolling ridges and valleys, and the soils vary in their productivity. Landcover includes intensive agriculture, urban and industrial uses, as well as areas of thick forest. White oak forest, bottomland oak forest, and sycamore-ash-elm riparian forests are the common forest types. Grassland barrens intermixed with cedar-pine glades also occur here.

67g The **Southern Shale Valleys** consist of lowlands, rolling valleys, slopes and hilly areas that are dominated by shale materials. The northern areas are associated with Ordovician-age calcareous shale, and the well-drained soils are often slightly acid to neutral. In the south, the shale valleys are associated with Cambrian-age shales that contain some narrow bands of limestone, but the soils tend to be strongly acid. Small farms and rural residences subdivide the land. The steeper slopes are used for pasture or have reverted to brush and forested land, while small fields of hay, corn, tobacco, and garden crops are grown on the foot slopes and bottom land.

67h The **Southern Sandstone Ridges** ecoregion encompasses the major sandstone ridges, but these ridges also have areas of shale and siltstone. The steep, forested ridges have narrow crests with soils that are typically stony, sandy, and of low fertility. The chemistry of streams flowing down the ridges can vary greatly depending on the geological material. The higher elevation ridges are in the north, including Wallen Ridge, Powell Mountain, Clinch Mountain and Bays Mountain. White Oak Mountain in the south has some sandstone on the west side, but abundant shale and limestone as well. Grindstone Mountain, capped by the Gizzard Group sandstone, is the only remnant of Pennsylvanian-age strata in the ridge and valley of Tennessee.

67i The **Southern Dissected Ridges and Knobs** contain more crenulated, broken, or hummocky ridges, compared to the smoother, more sharply pointed sandstone geologic materials. The ridges on the east side of Tennessee's Ridge and Valley tend to be associated with the Ordovician-age Sevier shale, Athens shale, and Holston and Lenoir limestones. These can include calcareous shale, limestone, siltstone, sandstone, and conglomerate. In the central and western part of Ecoregion 67i, the shale ridges are associated with the Cambrian-age Rome Formation: shale and siltstone with beds of sandstone. Chestnut oak forests and pine forests are typical for the higher elevations of the ridges, with areas of white oak, mixed mesophytic forest, and tulip poplar on the lower slopes, knobs, and draws.

68a The **Cumberland Plateau's** tablelands and open low mountains are about 1000 feet higher than the Eastern Highland Rim (71g) to the west, and receive slightly more precipitation with cooler annual temperatures than the surrounding lower-elevation ecoregions. The plateau surface is less dissected with lower relief compared to the Cumberland Mountains (69d) or the Plateau Escarpment (68c). Elevations are generally 1200-2000 feet, with the Crab Orchard Mountains reaching over 3000 feet. Pennsylvanian-age conglomerate, sandstone, siltstone, and shale is covered by well-drained, acid soils of low fertility. The region is forested with some agriculture and coal mining activities.

68b The **Sequatchie Valley** is structurally associated with an anticline, where erosion of broken rock to the south of the Crab Orchard Mountains scooped out the linear valley. The open, rolling, valley floor, 600-1000 feet in elevation, is generally 1000 feet below the top of the Cumberland Plateau. A low, central, cherty ridge separates the west and east valleys of Mississippian to Ordovician-age limestones, dolomites, and shales. Similar to parts of the Ridge and Valley (67), this is an agriculturally productive region, with areas of pasture, hay, soybeans, small grain, corn, and tobacco.

68c The **Plateau Escarpment** is characterized by steep, forested slopes and high velocity, high gradient streams. Local relief is often 1000 feet or more. The geologic strata include Mississippian-age limestone, sandstone, shale, and siltstone, and Pennsylvanian-age shale, siltstone, sandstone, and conglomerate. Streams have cut down into the limestone, but the gorge talus slopes are composed of colluvium with huge angular, slabby blocks of sandstone. Vegetation community types in the ravines and gorges include mixed oak and chestnut oak on the upper slopes, mesic forests on the middle and lower slopes (beech-tulip poplar, sugar maple-basswood-ash-buckeye), with hemlock along rocky streamsides and river birch along floodplain terraces.

69d The **Cumberland Mountains**, in contrast to the sandstone-dominated Cumberland Plateau (68a) to the west and southwest, are more highly dissected, with narrow-crested steep slopes, and younger Pennsylvanian-age shales, sandstones, siltstones, and coal. Narrow, winding valleys separate the mountain ridges, and relief is often 2000 feet. Cross Mountain, west of Lake City, reaches 3534 feet in elevation. Soils are generally well-drained, loamy, and acidic, with low fertility. The natural vegetation is a mixed mesophytic forest, although composition and abundance vary greatly depending on aspect, slope position, and degree of shading from adjacent landmasses. Large tracts of land are owned by lumber and coal companies, and there are many areas of stripmining. Acid mine drainage is primarily limited to first and second order systems. Siltation as surface run-off remains the primary pollutant from past mining, timber harvest and unpaved roads.

71e The **Western Pennyroyal Karst** is a flatter area of irregular plains, with fewer perennial streams compared to the open hills of the Western Highland Rim (71f). Small sinkholes and depressions are common. The productive soils of this highly agricultural area formed mostly from a thin loess mantle over Mississippian-age limestones. Most of the region is cultivated or in pasture. Tobacco and livestock are the principal agricultural products, with some corn, soybeans, and small grains. The natural vegetation consisted of oak-hickory forest with mosaics of bluestem prairie. The barrens of Kentucky that extended south into Stewart, Montgomery, and Robertson counties, were once some of the largest grasslands in Tennessee.

71f The **Western Highland Rim** is characterized by dissected, rolling terrain of open hills, with elevations of 400-1000 feet. The geologic base of Mississippian-age limestone, chert, and shale is covered by soils that tend to be cherty and acidic with low to moderate fertility. Streams are relatively clear with a moderate gradient. Substrates are coarse chert, gravel and sand with areas of bedrock. The native oak-hickory forests were removed over broad areas in the mid-to late 1800's in conjunction with the iron-ore related mining and smelting of the mineral limonite, however today the region is again heavily forested. Some agriculture occurs on the flatter interfluvies and in the stream and river valleys. The predominant land uses are hay, pasture, and cattle with some cultivation of corn and tobacco.

71g The **Eastern Highland Rim** has more level terrain than the Western Highland Rim (71f), with landforms characterized as tablelands of moderate relief and irregular plains. Mississippian-age limestone, chert, shale and dolomite predominate. Karst terrain sinkholes and depressions are especially noticeable between Sparta and McMinnville. Numerous springs and spring-associated fish fauna typify the region. Natural vegetation is transitional between the oak-hickory forests to the west and the mixed mesophytic forests of the Appalachian ecoregions (68, 69) to the east. Bottomland hardwoods forests were once abundant in some areas, although much of the original bottomland forest has been inundated by several large impoundments. Barrens and former prairie areas are now primarily oak thickets, pasture or cropland.

71h The **Outer Nashville Basin** is a more heterogeneous region than the Inner Nashville Basin (71I), with rolling and hilly topography with slightly higher elevations. The region encompasses most of the outer areas of the generally non-cherty Ordovician limestone bedrock. The higher hills and knobs are capped by the more cherty Mississippian-age formation, and some Devonian-age Chattanooga shale, remnants of the Highland Rim. The region's limestone rocks and soils are high in phosphorus, and commercial phosphate is mined. Deciduous forest with pasture and cropland are the dominant land covers. The region has areas of intense urban development with the city of Nashville occupying the northwest region. Streams are low to moderate gradient, with productive, nutrient-rich waters, resulting in algae, rooted vegetation, and occasionally high densities of fish. The Nashville Basin has a distinctive fish fauna, notable for fish that avoid the region, as well as those that are present.

71i The **Inner Nashville Basin** is less hilly and lower than the Outer Nashville Basin (71h). Outcrops of the Ordovician-age limestone are common. The generally shallow soils are redder and lower in phosphorous than those of the outer basin. Streams are lower gradient than surrounding regions, often flowing over large expanses of limestone bedrock. The most characteristic hardwoods within the inner basin are a maple-oak-hickory-ash-association. The limestone cedar glades of Tennessee, a unique mixed grassland/forest cedar glades vegetation type with many endemic species, are located primarily on the limestones of the Inner Nashville Basin. The more xeric, open characteristics and shallow soils of the cedar glades also result in a distinct distribution of amphibian and reptile species. Urban, suburban, and industrial land use in the region is increasing.

73a The **Northern Mississippi Alluvial Plain** within Tennessee is a relatively flat region of the Quaternary alluvial deposits of sand, silt, clay, and gravel. It is bounded distinctly on the east by the Bluff Hills (74a), and on the west by the Mississippi River. Average elevations are 200-300 feet with little relief. Most of the region is in cropland, with isolated areas of deciduous forest. Soybeans, cotton, corn, sorghum, and vegetables are the main crops. The natural vegetation consists of Southern floodplain forest (oak, tupelo, bald cypress). The two main distinctions in the Tennessee portion of the ecoregion are between areas of loamy, silty, and sandy soils with better drainage, and areas of more clayey soils of poor drainage that may contain wooded swamp-land and oxbow lakes. Waterfowl, raptors, and migratory songbirds are relatively abundant in the region.

74a The **Bluff Hills** consist of sand, clay, silt, and lignite, and are capped by loess greater than 60 feet deep. The disjunct region in Tennessee encompasses those thick loess areas that are generally the steepest, most dissected, and forested. The carved loess has a mosaic of microenvironments, including dry slopes and ridges, moist slopes, ravines, bottomland areas, and small cypress swamps. While oak-hickory is the general forest type, some of the undisturbed bluff vegetation is rich in mesophytes, such as beech and sugar maple, with similarities to hardwood forests of eastern Tennessee. Smaller streams of the Bluff Hills have localized reaches of increased gradient and small areas of gravel substrate that create aquatic habitats that are distinct from those of the Loess Plains (74b) to the east.

74b The **Loess Plains** are gently rolling, irregular plains, 250-500 feet in elevation, with loess up to 50 feet thick. The region is a productive agricultural area of soybeans cotton, corn, milo, and sorghum crops, along with livestock and poultry. Soil erosion can be a problem on the steeper, upland Alfisol soils. Bottom soils are mostly silty Entisols. Oak-hickory and southern floodplain forests are the natural vegetation types, although most of the forest cover has been removed for cropland. Some less-disturbed bottomland forest and cypress-gum swamp habitats still remain. Several large river systems with wide floodplains; the Obion, Forked Deer, Hatchie, Loosahatchie, and Wolf, cross the region. Streams are low-gradient and murky with silt and sand bottoms. Most of the streams have been channelized.

APPENDIX B

LIST OF CANDIDATE AND FINAL REFERENCE SITES

TENNESSEE CANDIDATE AND FINAL ECOREGION REFERENCE STREAMS

65. SOUTHEASTERN PLAINS

Sites in bold were selected as final reference streams

65a Blackland Prairie					
SITE #	STREAM/LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO♣65A01 ^^^	Unnamed trib. to Muddy Cr at Matt Dammonds Rd	08010207 Upper Hatchie	S. Central Miss. River	McNairy	Added 9/96
ECO♣65A02 ^^^	Little Owl Creek at Michie Pebble Hill Road or at Perkins Road (the southern trib.)	06040001 TN Western Valley (Beech)	Tennessee River	McNairy	Poor site, all ditched with extremely unstable banks and no habitat. Too much agriculture in watershed, no bank, riffle or snag habitat.
ECO♣65A03 ^^^	Wardlow Cr. at Hamburg Rd	06040001 TN West. Valley (Beech)	Tennessee River	McNairy	Added 9/96
ECO♣65A04 xxx	Wardlow Creek at Liberty Rd	06040001 TN Western Valley (Beech)	Tennessee River	McNairy	Good riparian zone and instream habitat, low flow but deep. Appears to be in 65e
ECO♣65A05 ^^^	Little Owl Cr. at Pebble Hill Rd	06040001 TN Western Valley (Beech)	Tennessee River	McNairy	Intensive agriculture, unstable banks, no habitat.

65b Flatwoods/Alluvial Prairie Margins					
SITE #	STREAM/LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO♣65B01 xxx	Magbee Branch at Lower Serles Road or Pea Vine Road	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Degraded by construction and farming, banks unstable, stream shallow.
ECO♣65B02 xxx	Colonel Fork at Highway 125	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Impact from possible industrial runoff and mining impacts at Highway 125.
ECO♣65B03 xxx	Upper unnamed trib. To Hatchie River at Pea Vine Rd	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Fairly good riparian, but bank instability and extreme sand load/flow fluctuations, scouring.
ECO♣65B04 ***	Cypress Creek at Buster King Road	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Added 9/96.
ECO♣65B05 zzz	Prairie Br at Pea Vine Rd	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Dropped due to impacts
ECO♣65B06 ^^^	Lower unnamed trib. to Hatchie River at Pea Vine Rd	08010207 Upper Hatchie	S. Central Miss. River	Hardeman	Moderate habitat availability including snag and bank habitat, banks were undercut indicating sporadic high flow.

65e Southeastern Plains and Hills					
SITE #	STREAM/LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO65E01 xxx	Gin Creek at Copper Spring Road, above Big Sandy River	06040005 TN Western Valley (Ky Lake)	Tennessee River	Henry	Appears almost all forested on map. Bank instability. Water clear in Natchez Trace State Park, turbid outside of park.
ECO65E02 ^^^	Slickup/Pettijohn Creek (trib. to Guins Cr) at Barham Rd	08010203 South Fork Obion	S. Central Miss. River	Henry	Slow flow, bank and riffle habitats available, beaver dam nearby, freshwater sponges indicate good water quality.
ECO65E03A xxx	Spring Creek at Highway 140, 3 mi N of McKenzie	08010203 South Fork Obion	S. Central Miss. River	Henry	Sections channelized, mining in watershed.
ECO65E03B xxx	Caledonia Creek at Verdell Store Road and Caledonia Rd	08010203 South Fork Obion	S. Central Miss. River	Henry	Impoundment built on stream 2 years ago, creek turbid.
ECO65E04 ***	Blunt Creek (trib. to Big Sandy River) above Clark Rd, 2 mi SE of Buena Vista	06040005 TN Western Valley (Ky Lake)	Tennessee River	Carroll	Added 9/96
ECO65E05 xxx	Coon Cr. (trib. to Birdsong Cr) at Highway 192 or above Old SR 69, 3 mi n of Holladay	06040005 TN Western Valley (Ky Lake)	Tennessee River	Benton	Too small with little flow, appeared to be choked with gravel. Stream is surrounded by agriculture.
ECO65E06 ^^^	Griffin Creek, Hwy 104 at Henderson/Carroll County line near Cedar Grove	08010204 South Fork Forked Deer	S. Central Miss. River	Henderson Carroll	Added 6/98
ECO65E07 xxx	Scarce Cr, at Scarce Creek Rd. trib. to Big Sandy, Timberlake Rd near Wildersville	06040005 TN Western Valley (Ky Lake)	Tennessee River	Henderson	Or move site into Natchez Trace State Forest. McNairy Sand geology, turbid outside of park, small flow.
ECO65E08 ***	Harris Creek, Potts Chapel Road, 7 mi east of Jackson	08010201 North Fork Forked Deer	S. Central Miss. River	Madison	Added 8/96.
ECO65E09 xxx	Spencer Creek, Spencer Creek Rd or upriver at Hammett Rd, 1 mi E of Beech Bluff near Madison Co. line	08010201 North Fork Forked Deer	S. Central Miss. River	Henderson	Not much flow, impoundment on creek.
ECO65E10 ***	Marshall Cr. (trib. to Snow Spring Cr) at Van Buren Rd, 3 mi e of Hickory Valley	08010208 Lower Hatchie	S. Central Miss. River	Hardeman	Added 8/96.
ECO65E11 ^^^	West Fork Spring Creek, Van Buren Rd, 3.5 mi north of Saulsburly	08010208 Lower Hatchie	S. Central Miss. River	Hardeman	Added 8/96
ECO65E12 ^^^	East Fork Spring Creek, Old State Line Road, 3 mi east of Saulsburly	08010208 Lower Hatchie	S. Central Miss. River	Hardeman	Narrow, fairly swift dark sandy substrates, watershed wooded.

65e Southeastern Plains and Hills cont.					
SITE #	STREAM/LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO65E13 xxx	Cypress Creek above Little Hatchie River at McNairy/Hardeman County line, 4 mi se of Hornsby	08010208 Lower Hatchie	S. Central Miss. River	McNairy	Small creek, nice meander. Too easily accessible to fishermen and campers. Unimproved private road. Beaver impoundment, ponded area at the confluence of Cypress Creek with Little Hatchie River.
ECO65E14 ^^^	Reedy Branch (trib. To Cypress Cr./ Tuscumbia Ri) at Blanship Road, 2 mi wnw of Ramer	08010208 Lower Hatchie	S. Central Miss. River	McNairy	Too small. Good flow, substrate sandy, possibly logging on one small trib.
ECO65E15 ***	Waldrop Creek (trib. to Chambers Cr.) at Hwy 142, 4 mi south of Southside	06030005 TN Pickwick Lake	Tennessee	McNairy Hardin	Most of watershed is in Tennessee but access is 400 yds. in Mississippi. Water appears very black, wetlands and beaver dam present
ECO♣65E16 xxx	Skipper Creek at Powell Chapel Road	08010208 Lower Hatchie	S. Central Miss. River	McNairy	No channelization apparent in the drainage area, does not reach Hatchie, beaver dams on streams, lack of flow.
ECO♣65E17 ^^^	Mosses Creek upstream of Vernie Taylor Road	08010208 Lower Hatchie	S. Central Miss. River	McNairy	Much channelization in the watershed, excellent riparian, primarily black sand substrate. Not wadeable, no boat access.
ECO♣65E18 ***	Hatchie River at Pocohontas	08010208 Lower Hatchie	S. Central Miss. River	McNairy	Wooded area provides good riparian, no channelization on the river, but tribs are channelized.
ECO♣65E19 xxx	Guins Creek at Barham Road	08010201 North Fork Obion	S. Central Miss. River	Carroll	Flow good, water clear, substrate diverse, but discharger in the far upstream reaches.

65i Fall Line Hills					
SITE #	STREAM/LOCATION		MAJOR BASIN	COUNTY	COMMENTS - DROPPED ECOREGION DUE TO SMALL SIZE OF ECOREGION
ECO♣65I01 333	Robinson Creek at Red Sulphur Road	06030005 TN Pickwick La)	Tennessee River	Hardin	Dropped due to impacts
ECO♣65I02 ***	Battles Branch at Old Kendrick Road	06030005 TN Pickwick La)	Tennessee River	Hardin	Added 9/96
ECO♣65I03 333	Unnamed trib. to East Fork Robinson Creek	06030005 TN Pickwick La)	Tennessee River	Hardin	Dropped due to impacts

65j Transition Hills					
SITE #	STREAM/LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO65J01 xxx	Whitlow-Turner-Alexander Br (trib. to Indian Cr) above Whitlow Rd, 3 mi east of Cerro Gordo	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Sandier bottom with less gravel than other streams in this subregion. Some agriculture at Whitlow Road, atypical of region, manure odor in the creek.
ECO65J02 ^^^	Turkey Creek below Gobbler Cr and Lone Pine, Center Star Road, 4 mi e of Burnt Church	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Open area with fallow fields, good variety of caddisflies and mayflies, some logging, substrates were primarily coarse gravel, some silt and sand in pools.
ECO65J03 xxx	Howard Br (trib. To Horse Cr) at Hwy 69, 3 mi se of Maddox	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Stream sluggish and ran through cow pasture, water appeared turbid and green.
ECO65J04 ***	Pompeys Br (trib. To Pickwick Lake) at Pompeys Br Rd	06030005 TN Pickwick Lake	Tennessee River	Hardin	Added 8/96
SITE #	STREAM/LOCATION		MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO65J05 ***	Dry Creek, Dry Creek Road	06030005 TN Pickwick Lake	Tennessee River	Hardin	Added 8/96
ECO65J06 ***	Right Fork Whites Creek above Morris Lane Road, 1 mi north of Walnut Grove	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Added 8/96
ECO65J07 ^^^	May Branch at May Branch Road, 3 mi east of Cypress Inn	06030004 Lower Elk	Tennessee River	Wayne	Downstream access in Alabama, some pasture and farming in the watershed. Size of the watershed is small.
ECO♣65J08 ^^^	Cypress Creek at Natchez Trace Parkway, RM 4.8 from state line	06030004 Lower Elk	Tennessee River	Wayne	Bank scouring, construction on Natchez Trace Parkway. Watershed is 80% protected because it flows along the Natchez Trace Parkway. Logging or growing of monoculture pines will probably not take place in this watershed. cursory examination of the benthics found a good assemblage.
ECO♣65J09 xxx	Grassy Creek on Grassy Creek Road	06030004 Lower Elk	Tennessee River	Wayne	Watershed within monoculture pine plantation and would not be acceptable as a reference stream. cursory benthic examination found a number of stoneflies.
ECO♣65J10 xxx	Gobbler Branch at Lonesome Pine Road	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Pine plantation and recent logging in watershed.
ECO♣65J11 ***	Unnamed trib Right Fork Whites Cr above Morris Lane Rd, 1 mi north of Walnut Grove, north branch	06040001 TN Western Valley (Beech)	Tennessee River	Hardin	Added 2/97.

66. BLUE RIDGE MOUNTAINS

66d Southern Igneous Ridges and Mountains					
SITE #	STREAM / LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO66D01 ***	Black Branch (trib. to Row Branch, Elk River), above Hwy 321 near Elk Mills	06010103 Watauga	Tennessee River	Carter	Added 8/96
ECO66D02 xxx	Heaton Branch (trib. to Elk River), Heaton Branch Road, near Elk Mills	06010103 Watauga	Tennessee River	Carter	Not fully protected. Road parallels most of the stream.
ECO66D03 ***	Laurel Fork (Doe River), above Big Branch and Dennis Cove Road across from campground	06010103 Watauga	Tennessee River	Carter	Added 8/96
ECO66D04 xxx	Big Bald Creek (trib. to Coffee Ridge Creek), Farnor Road, 3 mi south of Ernestville	06010108 Nolichucky	Tennessee River	Unicoi	Streams in this part of 66D look more disturbed with roads and clearings. Logging immediately along the stream.
ECO66D05	Doe River, in Cherokee NF, along Hwy 19	06010103 Watauga	Tennessee River	Carter	Added 5/98
ECO♣66D06	Tumbling Creek	06010108 Nolichucky	Tennessee River	Carter	Added 11/97, benthics only
ECO♣66D07	Little Stoney Creek	06010103 Watauga	Tennessee River	Carter	Added 11/97, benthics only

66e Southern Sedimentary Ridges					
SITE #	STREAM / LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS
ECO66E01	Lyons Branch, above Laurel Cr, Hwy 91, 1.5 mi north of Laurel Bloomery	06010102 South Fork Holston	Tennessee River	Johnson	Unable to locate this stream. The drainage area is very small.
ECO66E02 xxx	Chalk Branch, at Highway 133, 4 mi south of Sutherland (trib. to Beaverdam Creek)	06010102 South Fork Holston	Tennessee River	Johnson	The drainage area is very small.
ECO66E03 xxx	Fagall Branch, at Highway 133, above Beaverdam Creek	06010102 South Fork Holston	Tennessee River	Johnson	Because of its small size, it would not make a good fisheries reference. Birch Branch to the south is an alternative, or tribs to Beaverdam Creek across from Fagall Branch.
ECO66E04 ^^^	Gentry Cr, below Grindstone Br 2.5 mi se of Laurel Bloomery	06010102 South Fork Holston	Tennessee River	Johnson	Sampled 11/97 only
ECO66E05 xxx	Morgan Br, 3/4 mi above Big Dry Run, east of Watauga Lake	06010103 Watauga	Tennessee River	Johnson	Recommended by Dean Whitworth-Sierra Club. Big Dry Run has poor (30) TVA-IBI score. Stream not good fisheries reference because of its size, also on private land.

66e Southern Sedimentary Ridges cont.					
SITE #	STREAM / LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS
ECO66E06 xxx	Pine Bottom Branch, above Watauga River/Lake	06010103 Watauga	Tennessee River	Johnson	Recommended by Dean Whitworth-Sierra Club. Access would require boat to cross Watauga River/Lake.
ECO66E07 xxx	Little Stony Cr (trib. to Stony Cr.) via FR 202A above Hunter, 5 mi ne of Elizabethton	06010103 Watauga	Tennessee River	Carter	Near-stream forest road. Miller or Laurel Br to the E near Carter may be less impacted, densely populated resid./agric. area.
ECO66E08 xxx	Rat Br, (trib. to south shore Watauga Lake by Appalachian Trail), above Hwy 321/67, 2.5 mi ne of Braemar	06010103 Watauga	Tennessee River	Carter	Drainage area very small. Stream was dry in August, flow goes underground in December.
ECO66E09 ***	Clark Creek via Clarks Cr Rd and Forest Rd 25, 3 mi sw of Bumpus Cove	06010108 Nolichucky	Tennessee River	Unicoi	Added 8/96
ECO66E10 ^^^	Granny Lewis Cr (trib. to South Indian Cr), 2 mi nw of Ernestville	06010108 Nolichucky	Tennessee River	Unicoi	Watershed lies within Cherokee National Forest, heavy impact at site observed, possibly better upstream good alternative reference stream.
ECO66E11 ***	Lower Higgins Cr (trib. to South Indian Cr), via Lower Higgins Cr Road, 1 mi nw of Ernestville	06010108 Nolichucky	Tennessee River	Unicoi	Added 8/96.
ECO66E12 xxx	Cassi Cr (trib. to Nolichucky River), Sampson Mountain Wilderness via Cassi Road, 2 mi south of Liberty	06010108 Nolichucky	Tennessee River	Green	Stream too small. Classified as naturally reproducing trout stream. Impacted by residential/agricultural areas.
ECO66E13 xxx	Dry Creek (trib. to Camp Cr), above Mission Rd, 2 mi south of Bethany	06010108 Nolichucky	Tennessee River	Green	Ecoregion boundary is about 1/4 mile upstream from Mission Road.

SITE #	STREAM / LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO74A01 xxx	Indian Creek above Old Samburg Road	08010202 Obion	S. Central Miss. River	Obion	Stream is impounded as a lake. No access, sheer bluffs.
ECO74A02 xxx	Carrol Creek above PawPaw Creek	08010202 Obion	S. Central Miss. River	Obion	Access via Putnam Hill Road and Pawpaw Creek could be difficult. Channel is too small and undefined, sheer bluffs.
ECO74A03 xxx	Brown Creek above Cat Corner, Lasiter Foothill Road	08010202 Obion	S. Central Miss. River	Obion	Small, sluggish stream, excellent riparian. Large fields on both sides. PVC pipe was in stream. Strong chemical odor (pesticides). Old unlined landfill present in watershed.
ECO74A04 xxx	Possum Creek above Coon Creek at Lenox-Nauvoo Road	08010202 Obion	S. Central Miss. River	Dyer	May be too small. Surrounding land use pasture and forest. Hog pens and cars in stream. Coon Creek has a reservoir.
ECO74A05 xxx	Knob Creek at Porter Gap Road	08010100 Mississippi	S. Central Miss. River	Lauderdale	Excessive green algal growth, impacted by some nutrient source. Extensive bulldozer work around bridge site.
ECO74A06 ^^^	Sugar Creek, Highway 59	08010100 Mississippi	S. Central Miss. River	Tipton	Added 4/96
ECO74A07 ^^^	Bear Cr above Bluff Road, 3 mi SW of Drummonds	08010100 Mississippi	S. Central Miss. River	Tipton	Lots of agriculture in watershed, septic tank impacting streams.
ECO♣74A08 ***	PawPaw Creek upstream confluence with Carroll Cr.	08010202 Obion	Mississippi	Obion	Added 8/96
ECO♣74A09	Unnamed trib. to Brinkley Bayou, in Meeman Shelby SP	08010100 Mississippi	S. Central Miss. River	Shelby	Small wadeable stream. Sediment is predominately sand with gravel

ECO*74A10 333	Unnamed trib. to Running Reelfoot Bayou	08010202 Obion	S. Central Miss. River	Obion	Dropped small, spring like, atypical
-------------------------	--	---------------------------------	------------------------	--------------	---

74B Loess Plains					
SITE #	STREAM / LOCATION	USGS HUC CODE	MAJOR BASIN	COUNTY	COMMENTS (Initial Screening)
ECO74B01 ^^^	Terrapin Creek above Highway 69	08010202 Obion	S. Central Miss. River	Henry	Added 9/96
ECO74B02 xxx	Sugar Creek at N Fork Church Road (trib. to Terrapin Creek)	08010202 Obion	S. Central Miss. River	Henry	May be too small. Some channelization, agricultural impacts, but appears to have relatively more riparian forest.
ECO74B03 xxx	Biggs / Hurricane Creek at Hwy 89, 3.5 mi N of Palmersville; or downstream	08010202 Obion	S. Central Miss. River	Weakley	It had a curve or two and a small patch of green, but probably too impacted. Channelized.
ECO74B04 ^^^	Powell Cr at McLains Levee Road	08010202 Obion	S. Central Miss. River	Weakley	Added 9/96.
ECO74B05 xxx	Unnamed tributary to N Fork Obion River, at Highway 118, 1 mi N of Latham	08010202 Obion	S. Central Miss. River	Weakley	Small watershed. Recent logging, iron flocculant. Upper half is all ag with some channelization, lower half meanders and is forested into the N Fork Obion floodplain.
ECO74B06 ^^^	Lagoon Creek at Estes Lane, 12 mi W of Brownsville	08010208 Lower Hatchie	S. Central Miss. River	Haywood	Channelization of tribs and ag. impacts in the upper watershed impact this creek.
ECO74B07 xxx	Cypress Cr at Herbert Willis Rd or next upstream crossing, 9 mi W of Brownsville	08010208 Lower Hatchie	S. Central Miss. River	Haywood	Too much agriculture in the watershed.
ECO74B08 xxx	Unnamed trib to Jeffers Cr, 1st trib. above Bachelor Levee Rd at Harold Stanley Rd near Haywood/Madison county line	08010208 Lower Hatchie	S. Central Miss. River	Haywood Madison	No trespassing signs on land, plowed fields.
ECO74B09 xxx	Little Muddy Creek in Hatchie Bottom	08010208 Lower Hatchie	S. Central Miss. River	Haywood	Too small, too little flow, access a problem. Small unimproved road from Post Road.
ECO74B10 xxx	East Beaver Cr above Hendrick Rd, 1/2 mi SE of Mason	08010209 Loosahatchie	S. Central Miss. River	Tipton	Channel degradation.
ECO74B11 xxx	Unnamed trib to Wolf River at Knox Road, 3.5 mi SSW of Rossville, 1/2 mi N of state line	08010210 Wolf	S. Central Miss. River	Fayette	Channel degradation.
ECO74B12 ^^^	Wolf River upstream Yager Rd, 1 mi S of La Grange	08010210 Wolf	S. Central Miss. River	Fayette	Added 9/96
ECO*74B13 xxx	Original meander of the N Fork Obion, 0.75 mi N of Latham on Highway 118	08010202 Obion	S. Central Miss. River	Weakley	Iron floc was present, plowed fields near stream. Old meander of original river, more typical of bigger streams in Loess area.

Sites in bold were selected as final reference streams

Legend

- ☹☹ Site dropped after sampling due to impacts
- ♣ Site not on EPA candidate list, added by WPC or other agencies
- *** Good Candidate Reference Stream
- ^^^ Probably not a good reference stream, but keep in mind
- xxx Eliminate from consideration

STORET# _____		AGENCY _____	
INVESTIGATORS _____		_____	
FORM COMPLETED BY _____		DATE _____	REASON FOR SURVEY _____
		TIME _____ AM PM	

Habitat Parameter	Condition Category			
	Optimal	Suboptimal	Marginal	Poor
1. Epifaunal Substrate/Available Cover	Greater than 70% of substrate favorable for epifaunal colonization and fish cover; mix of snags, submerged logs undercut banks, cobble or other stable habitat and at stage to allow full colonization potential (i.e., logs/snags that are not new fall and not transient)	40-70% mix of stable habitat; well-suited for full colonization potential; adequate habitat for maintenance of populations; presence of additional substrate in the from of newfall, but not yet prepared for colonization (may rate at high end of scale)	20-40% mix of stable habitat; availability less than desirable; substrate frequently disturbed or removed	Less than 20% stable habitat; lack of habitat is obvious; substrate unstable or lacking
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1
2. Embeddedness	Gravel, cobble, and boulder particles are 0-25% surrounded by fine sediment. Layering of cobble provides diversity of niche space.	Gravel, cobble and boulder particles are 25-50% surrounded by fine sediment.	Gravel, cobble, and boulder particles are 50-75% surrounded by fine sediment.	Gravel, cobble, and boulder particles are more than 76% surrounded by fine sediment.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1
3. Velocity/Depth Regime	All four velocity/depth regimes present (slow-deep, slow-shallow, fast-deep, fast-shallow) (Slow is <0.3m/s deep is >0.5m)	Only 3 of the 4 regimes present (if fast-shallow is missing score lower than regimes).	Only 2 of the 4 habitat regimes present (if fast-shallow or slow-shallow are missing, score low)	Dominated by 1 velocity/depth regime (usually slow-deep)
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1
4. Sediment Deposition	Little or no enlargement of islands or point bars and less than 5% (<20% for low -gradient streams) of the bottom affected by sediment deposition	Some new increase in bar formation, mostly from gravel, sand or fine sediment; 5-30% (20-50% for low-gradient) of the bottom affected; slight deposition in pools	Moderate deposition of new gravel, sand/or fine sediment on old and new bars; 30-50% (50-80% for low-gradient) of the bottom affected; sediment deposits at obstructions, constrictions, and bends; moderate deposition of pools	Heavy deposits of fine material, increased far development; more than 50% (80% for low-gradient) of the bottom changing frequently; pools almost absent due to substantial sediment deposition
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1
5. Channel Flow Status	Water reaches base of both lower banks, and minimal amount of channel substrate is exposed.	Water fills > 75% of the available channel; or 25 % of channel substrate is exposed.	Waters fills 25-75 % of the available channel, and/or riffle substrates are mostly exposed.	Very little water in channel and mostly present as standing pools.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1

HABITAT ASSESSMENT DATA SHEET- HIGH GRADIENT STREAMS (BACK)

Habitat Parameter	Condition Category																			
	Optimal					Suboptimal					Marginal					Poor				
6. Channel Alteration	Channelization or dredging absent or minimal; stream with normal pattern.					Some channelization usually near bridge abutments; evidence of past channelization, i.e., dredging, (greater than past 20 yr) may be present, but recent channelization not present					Channelization may be extensive; embankments or shoring structures, present on both banks; and 40 to 80% of stream reach channelized and disrupted.					Banks shored with gabion or cement; over 80% of the stream reach channelized and disrupted. Instream habitat greatly altered or removed entirely.				
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
7. Frequency of Riffles (or bends)	Occurrence of riffles frequent; ratio of distance between riffles divided by stream width <7:1 (generally 5-7); variety of habitat is key. If riffles are continuous, placement of boulders or other large, natural obstruction is important.					Occurrence of riffles infrequent; distance between riffles divided by the width of the stream is between 7 to 15.					Occasional riffle or bend; bottom contours provide some habitat; distance between riffles divided by the width of the stream is between 15 to 25.					Generally all flat water or shallow riffles; poor habitat; distance between riffles divided by the width of the stream is a ratio of >35.				
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
8. Bank Stability (score each bank) Note: determine left or right side by facing downstream.	Banks stable; evidence of erosion or bank failure absent or minimal; little potential for future problems <5% of bank affected.					Moderately stable; infrequent, small areas of erosion mostly healed over. 5-30% of bank in reach has areas of erosion.					Moderately unstable; 30-60 % of bank in reach has areas of erosion; high erosion potential during floods					Unstable; many eroded area; "raw" areas frequent along straight sections and bends; obvious bank sloughing; 60-100% of bank has erosional scars				
SCORE____(LB)	Left Bank	10	9			8	7	6			5	4	3			2	1	0		
SCORE____(RB)	Right Bank	10	9			8	7	6			5	4	3			2	1	0		
9. Vegetative Protective (score each bank) Note: determine left or right side by facing downstream	More than 90% of the streambank surfaces and immediate riparian zone covered by native vegetation, including trees, understory shrubs, or nonwoody macrophytes; vegetative disruption through grazing or mowing minimal or not evident; almost all plants allowed to grow naturally.					70-90% of the streambank surfaces covered by native vegetation, but one class of plants is not well-represented; disruption evident but not affecting full plant growth potential to any great extent; more than one-half of the potential plant stubble height remaining.					50-70% of the streambank surfaces covered by vegetation; disruption obvious; patches of bare soil or closely cropped vegetation common; less than one-half of the potential plant stubble height remaining					Less than 50% of the streambank surfaces covered by vegetation; disruption of streambank vegetation is very high; vegetation has been removed to 5 centimeters or less in average stubble height				
SCORE____(LB)	Left Bank	10	9			8	7	6			5	4	3			2	1	0		
SCORE____(RB)	Right Bank	10	9			8	7	6			5	4	3			2	1	0		
10. Riparian Vegetative Zone Width (score each bank riparian zone)	Width of riparian zone > 18 meters; human activities (i.e. parking lots, roadbeds, clear-cuts, lawns or crops) have not impacted zone					Width of riparian zone 12-18 meters; human activities have impacted zone only minimally					Width of riparian zone 6-12 meters; human activities have impacted zone a great deal.					Width of riparian zone <6 meters: little or no riparian vegetation due to human activities.				
SCORE____(LB)	Left Bank	10	9			8	7	6			5	4	3			2	1	0		
SCORE____(RB)	Right Bank	10	9			8	7	6			5	4	3			2	1	0
