## **DEPARTMENT OF ENVIRONMENT AND CONSERVATION**

### **Division of Water Pollution Control**

## **Quality System Standard Operating Procedure**

**for**

## **MACROINVERTEBRATE STREAM SURVEYS**

**2011**

This SOP is an intra-departmental document intended to govern the internal management of the Tennessee Department of Environment and Conservation and to meet requirements of the U.S. Environmental Protection Agency for a quality system. It is not intended to affect rights, privileges, or procedures available to the public.

As a part of the internal review process, the following individuals reviewed this document

**Tennessee Department of Environment and Conservation**

**Division of Water Pollution Control**

Paul Davis, Director

Garland Wiggins, Deputy Director

Gregory Denton, Environmental Program Manager I, Planning and Standards Section

Deborah Arnwine, Environmental Specialist 5, Planning and Standards Section

Linda Cartwright, Biologist 3, Planning and Standards Section

Chuck Head, Quality Assurance Manager

Chad Augustin, Biologist 4, Columbia Environmental Field Office

Joellyn Brazile, Environmental Specialist 4, Memphis Environmental Field Office

Beverly Brown, Biologist 4, Johnson City Environmental Field Office

Jonathon Burr, Environmental Field Office Manager, Knoxville Environmental Field Office

Brandon Chance, Biologist 4, Cookeville Environmental Field Office

Amy Fritz, Environmental Specialist 5, Jackson Environmental Field Office

Dan Murray, Biologist 4, Knoxville Environmental Field Office, Mining Section

Tina Robinson, Environmental Specialist 6, Johnson City Environmental Field Office

Kim Sparks, Environmental Specialist 4, Nashville Environmental Field Office

Dick Urban, Environmental Field Office Manager, Chattanooga Environmental Field Office

Terry Whalen, Environmental Specialist 6, Chattanooga Environmental Field Office

Jimmy Smith, Environmental Specialist 5, Nashville Environmental Field Office

Annie Goodhue, Biologist 3, Nashville Environmental Field Office

Brad Smith, Biologist 3, Jackson Environmental Field Office

Robin Cooper, Environmental Specialist 3, Johnson City Environmental Field Office

Amanda Whitley, Biologist 3, Planning and Standards Section

Michael Graf, Environmental Specialist 3, Planning and Standards Section

**Tennessee Department of Health Environmental Laboratory**

David Stucki, Manager, Aquatic Biology Section, retired

Pat Alicea, Manager, Aquatic Biology Section

Carrie Perry, Biologist 3, Aquatic Biology Section

Seton Bonney, Biologist 3, Aquatic Biology Section

Keith Gaddes, Biologist 3, Aquatic Biology Section

Tim McCollum, Biologist 3, Aquatic Biology Section

**Environmental Consulting**

Wendell Pennington, Pennington and Associates, Inc.

## **REVISIONS AND ANNUAL REVIEW PROCEDURE: QS-SOP FOR MACROINVERTEBRATE STREAM SURVEYS**

1. This document shall be reviewed annually to reconfirm the suitability and effectiveness of the program components described in this document.
2. A report of the evaluation of effectiveness of this document shall be developed at the time of review and submitted to appropriate stakeholders. Peer Reviews shall be conducted, if necessary and appropriate. It shall be reconfirmed that the document is suitable and effective. It shall include, if necessary, clarification of roles and responsibilities, response to problem areas and acknowledgement of successes. Progress toward meeting TDEC–BOE mission, program goals and objectives shall be documented. Plans shall be made for the upcoming cycle and communicated to appropriate stakeholders.
3. The record identified as “Revisions” shall be used to document all changes.
4. A copy of any document revisions made during the year shall be sent to all appropriate stakeholders. A report shall be made to the Assistant Commissioner and Quality Assurance Manager of any changes that occur. Other stakeholders shall be notified, as appropriate and documented on the “Document Distribution” list.

## NOTICE OF REVISION(S) RECORD 2006

| <b>Date</b> | <b>Specific Section or Page</b> | <b>Revision Type (major or minor)</b> | <b>Revision Description</b>   |
|-------------|---------------------------------|---------------------------------------|---|
| 10-1-03     | xii                             | Minor                                 | Replace MEFO recipient  |
| 10-01-03    | II/B/1                          | Minor                                 | Clarify Station Naming Protocol   |
| 10-01-03    | II/D/4                          | Minor                                 | Additional Information for Habitat Assessments  |
| 10-01-03    | II/D/5 Table 1                  | Major                                 | Revised Regional Habitat Guidelines   |
| 10-01-03    | II/F/5                          | Major                                 | Provide Biorecon Scoring Guidelines for 73a   |
| 10-01-03    | II/F/6 Table 2                  | Major                                 | Revised family level biorecon assessment guidelines   |
| 10-01-03    | II/F/8 Table 3                  | Major                                 | Revised Genus level biorecon assessment guidelines  |
| 10-01-03    | II/G/1                          | Minor                                 | Add online assessment database as source for determining ecoregions.                        |
| 10-01-03    | II/G/2                          | Minor                                 | Clarify procedures for additional SQKICK sampling to insure 200 organisms sample.           |
| 10-01-03    | II/G/4                          | Minor                                 | Clarify procedures for additional modified SQKICK sampling to insure 200 organism sample    |
| 10-01-03    | II/G/5                          | Minor                                 | Clarify procedures for additional SQBANK sampling to insure 200 organism sample.            |
| 10-01-03    | Appendix A 2-7                  | Major                                 | Updated biocriteria tables.   |
| 10-01-03    | Appendix A 8-14                 | Major                                 | Added location and status to ecoregion reference stream table. Added new reference streams. |
| 10-01-03    | Appendix A 15-16                | Major                                 | Added Table of regional expectations for individual habitat parameters.                     |
| 10-01-03    | Appendix B 4-7                  | Minor                                 | Revised header information on habitat assessment field sheets.                              |
| 03-03-03    | Appendix B 12                   | Minor                                 | Revised macroinvertebrate assessment report sheet.  |
| 10-01-03    | Appendix C 2                    | Major                                 | Added Peltoperlidae to list of intolerant macroinvertebrate families for biorecons.         |
| 10-01-03    | Appendix C 3-6                  | Major                                 | Updated intolerant macroinvertebrate genera for biorecons.                                  |

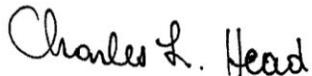

| <b>Date</b> | <b>Specific Section or Page</b>               | <b>Revision Type (major or minor)</b> | <b>Revision Description</b>  |
|-------------|---|---------------------------------------|--|
| 10-01-03    | Appendix C<br>7-21                            | Major                                 | Updated NCBI scores for Tennessee Taxa.  |
| 10-01-03    | Appendix C<br>22-25                           | Major                                 | Added taxa to list of clinger organisms.   |
| 10-01-03    | Appendix E                                    | Major                                 | Added taxa to verified taxa list.  |
| 10-12-06    | V   | Minor                                 | Change Commissioner's name   |
| 10-12-06    | V   | Minor                                 | Change QA manager's name.  |
| 10-12-06    | VIII  | Minor                                 | Update reviewers   |
| 10-12-06    | X   | Minor                                 | Update notice of revisions.  |
| 10-12-06    | Section 1.1,<br>Protocol B,<br>Page 2         | Minor                                 | Add naming scheme of UT to UT  |
| 10-12-06    | Section 1.1,<br>Protocol C,<br>Page 1         | Minor                                 | Update meter specifications to match chemical QSSOP.   |
| 10-12-06    | Section 1.1,<br>Protocol F,<br>page 4         | Minor                                 | Clarify how chironomids are counted in richness metric for biorecons.  |
| 10-12-06    | Section 1.1,<br>Protocol F,<br>Page 6 and 7   | Major                                 | Tables 2 and 3 updated based on reference data.  |
| 10-12-06    | Section 1.1,<br>Protocol J<br>Page 2          | Minor                                 | Clarification of Slide labeling procedure.   |
| 10-12-06    | Section II,<br>Protocol K<br>Page 2<br>Item f | Major                                 | %NUTOL replaced %Dominant  |
| 10-12-06    | Appendix A                                    | Major                                 | Biocriteria tables updated based on new reference data. Tables separated by season, metric ranges and target scores adjusted. Bioregion 66f combined with 66deg. |
| 10-12-06    | Appendix A                                    | Major                                 | Update ecoregion reference stream list.  |
| 10-12-06    | Appendix B                                    | Minor                                 | Revised header information on habitat assessment field sheets, stream survey field sheet and biorecon field sheet.   |

| Date     | Specific Section or Page | Revision Type (major or minor) | Revision Description                         |
|----------|--------------------------|--------------------------------|--|
| 10-12-06 | Appendix B               | Minor                          | Macroinvertebrate Assessment report revised. |
| 10-12-06 | Appendix C               | Minor                          | Added additional taxa to NCBI score list.    |
| 10-12-06 | Appendix C               | Minor                          | Added Nymphoridae to list of clingers.       |
| 10-12-06 | Appendix E               | Minor                          | Added taxa to the verified taxa list.        |

### NOTICE OF REVISION(S) RECORD 2011

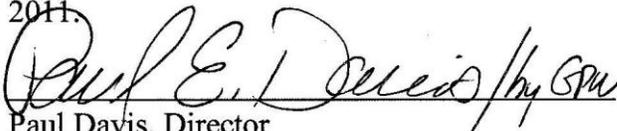

| Date     | Specific Section or Page | Revision Type (major or minor) | Revision Description  |
|----------|--------------------------|--------------------------------|---|
| 10-21-10 | Section I.D              | Minor                          | Updated Health and Safety Warnings and Cautions.  |
| 10-21-10 | Section II.A             | Minor                          | Added provision to relocate ecoregion reference sites upstream if localized problem develops. |
| 10-21-10 | Section I.C              | Minor                          | Added definitions and acronyms.   |
| 10-21-10 | Section I.I Protocol .A  | Major                          | Added sample priority list.   |
| 10-21-10 | Section I.I Protocol A   | Major                          | Added biological sample decision making flowcharts.   |
| 10-21-10 | Section I.I Protocol A   | Minor                          | Added provision for intermittent discharges to site selection protocol.                       |
| 10-21-10 | Section I.I Protocol A   | Minor                          | Clarified site selection.   |

| <b>Date</b> | <b>Specific Section or Page</b>              | <b>Revision Type (major or minor)</b> | <b>Revision Description</b>  |
|-------------|--|---------------------------------------|--|
| 10-21-10    | Section I.I<br>Protocol B                    | Minor                                 | Added quick field reference method summary.  |
| 10-21-10    | Section I.I<br>Protocol B                    | Minor                                 | Updated station naming protocols.  |
| 10-21-10    | Section I.I.<br>Protocol D<br>Table 2.       | Major                                 | Re-calibrated habitat assessment guideline scores. Removed impairment categories.  |
| 10-21-10    | Section I.I<br>Protocol D<br>Table 2.        | Major                                 | Added habitat assessment guidelines for headwater streams.                         |
| 10-21-10    | Section I.I<br>Protocol D<br>Appendix B      | Major                                 | Revised habitat assessment protocols and field sheets.                             |
| 10-21-10    | Section I.I<br>Protocol F                    | Major                                 | Revised biorecon voucher requirements for family.                                  |
| 10-21-10    | Section I.I<br>Protocol F                    | Minor                                 | Clarified biometric calculation information.                                       |
| 10-21-10    | Section I.I<br>Protocol F<br>Tables 3 and 4. | Major                                 | Recalibrated biorecon scoring guidelines.  |
| 10-21-10    | Section I.I<br>Protocol F<br>Tables 3 and 4. | Major                                 | Added biorecon scoring guidelines for headwater streams.                           |
| 10-21-10    | Section I.I<br>Protocol G                    | Minor                                 | Added shallow streams to modified kick protocol.                                   |
| 10-21-10    | Section I.I<br>Protocol H.                   | Major                                 | Added supply and bottle acquisition procedure.                                     |
| 10-21-10    | Section I.I<br>Protocol H                    | Minor                                 | Updated logging information.   |
| 10-21-10    | Section I.I<br>Protocol H                    | Minor                                 | Added sample transport information to protocol H.                                  |
| 10-21-10    | Section I.I.<br>Protocol J                   | Minor                                 | Clarified report preparation information. Added digital picture submittal.         |
| 10-21-10    | Section I.I<br>Protocol L                    | Major                                 | Added protocol for scoring SQSH in streams that do not fit biocriteria guidelines. |
| 10-21-10    | Section I.I.<br>Protocol L<br>Appendix A     | Major                                 | Calibrated %NUTOL to Tennessee taxa, renamed %TNUTOL.                              |

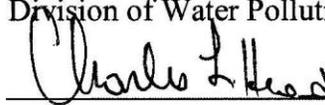

| <b>Date</b> | <b>Specific Section or Page</b>          | <b>Revision Type (major or minor)</b> | <b>Revision Description</b>   |
|-------------|--|---------------------------------------|---|
| 10-21-10    | Section I.I.<br>Protocol L<br>Appendix A | Major                                 | Replace %EPT with %EPT-Cheum.   |
| 10-21-10    | Section I.I.<br>Protocol L               | Minor                                 | Rearranged order of biometrics to correspond with biometrics tables.  |
| 10-21-10    | Section I.I<br>Protocol L                | Major                                 | Removed biological condition table 4.<br>Added information on index interpretation (pass/fail).                 |
| 10-21-10    | Section I.J.                             | Minor                                 | Update data and records management.   |
| 10-21-10    | Section I.I<br>Protocol M                | Major                                 | Added protocols for reference stream site selection.  |
| 10-21-10    | Section II                               | Major                                 | Added corrective actions to QA/QC.  |
| 10-21-10    | Appendix A                               | Minor                                 | Updated reference streams table. Added headwater reference stream table.  |
| 10-21-10    | Appendix B                               | Minor                                 | Added list of exotic plants.  |
| 10-21-10    | Appendix B                               | Minor                                 | Revised macroinvertebrate assessment report.  |
| 10-21-10    | Appendix C                               | Major                                 | Updated Appendix C  |
| 10-21-10    | Appendix D                               | Minor                                 | Updated taxonomic keys  |
| 01-06-11    | Appendix C<br>and E                      | Major                                 | Combined Verified taxa list, NCBI scores and clinger designation into one list called Tennessee taxa list 2011. |
| 02-09-11    | Section I.H                              | Minor                                 | Changed alcohol acquisition procedure.  |
| 02-09-11    | Section I.I.                             | Minor                                 | Changed procedure for transporting samples to lab.  |
| 5-2-11      | Section I.C and<br>I.I Protocol E        | Minor                                 | Clarified location of canopy measurements.  |
| 5-2-11      | Section I.I<br>Protocol A                | Minor                                 | Clarified sample priorities.  |
| 5-2-11      | Section I.I<br>Protocol B                | Minor                                 | Clarified stream mile measurements.   |
| 5-2-11      | Section I.I<br>Protocol B                | Major                                 | Revised naming protocols for unnamed tribs.   |

| Date    | Specific Section or Page             | Revision Type (major or minor) | Revision Description   |
|---------|--------------------------------------|--------------------------------|--|
| 5-2-11  | Section I.I Protocol D               | Major                          | Added further clarification for scoring of habitat assessments especially for channel flow status and channel alteration categories. |
| 5-2-11  | Section I.I Protocol F               | Minor                          | Added clarification in biorecon method.  |
| 5-2-11  | Section I.I Protocol F Table 4 and 5 | Major                          | Recalibrated scoring criteria for family and genus level biorecons.  |
| 5-2-11  | Section I.I Protocol G               | Minor                          | Added clarification in SQSH method.  |
| 5-2-11  | Section II                           | Major                          | Added clarification for biorecon vouchers and reference collections.   |
| 5-2-11  | Appendix A                           | Major                          | Revised biocriteria tables (drainage area, taxonomic level, recalibrated ranges). Added headwater tables.                            |
| 5-2-11  | Appendix B                           | Major                          | Revised stream survey field sheet.   |
| 5-2-11  | Appendix B                           | Major                          | Revised Habitat assessments field sheets to further clarify category scoring.  |
| 5-2-11  | Appendix B                           | Major                          | Revised biorecon field sheet   |
| 5-2-11  | Appendix E                           | Major                          | Added criteria for taxonomic experts adapted from NABs.  |
| 5-16-11 | Section I.I Protocol J               | Minor                          | Clarification of tolerance value sources for North Carolina Biotic Index.  |
| 5-25-11 | Appendix D                           | Minor                          | Added supplemental taxonomic keys<br>Updated list of taxonomic specialists   |

This revision has been reviewed and approved. It becomes effective on July 1, 2011.

## QS-SOP DOCUMENT DISTRIBUTION LIST

Copies of this document were distributed to the following individuals in TDEC and TDH

Additional copies were distributed to non-TDEC agencies and individuals upon request (including other state and federal agencies, consultants, universities etc.). An updated distribution list is maintained in the Planning and Standards Section.

The system for document distribution is described in TDEC-BOE Quality Manual, Chapters 5 and 10.

## **PREFACE**

The U.S. EPA requires that a centrally planned, directed and coordinated quality assurance and quality control program be applied to efforts supported by them through grants, contracts or other formalized agreements. This includes the implementation of a Quality Management Plan as written by the contract holder with Data Quality Objectives (DQOs) set in Quality Assurance Project Plans (QAPPs) for specific projects. The organization may elect to support portions of the QAPP through technical or administrative standard operating procedures (SOPs), as specified by the quality system. As a contract holder and through memoranda of agreement, the Tennessee Department of Environment and Conservation is required to maintain such a system.

This quality system technical Standard Operating Procedure (QS-SOP) was prepared, reviewed and distributed in accordance with TDEC's Quality Management Plan and other quality system documents in response to U.S. EPA's requirements for a Quality Management Program. QS-SOPs are integral parts of successful quality systems as they provide staff with the information to perform a job properly and facilitate consistency in the quality and integrity of the process.

This QS-SOP is specific to the Division of Water Pollution Control and is intended to assist the division in maintaining their quality control and quality assurance processes and ensure compliance with government regulations. It provides specific operational direction for the division's Quality Assurance Project Plan for Macroinvertebrate Stream Surveys.

## **I. PROCEDURES**

### **I.A SCOPE, APPLICABILITY AND REGULATORY REQUIREMENTS**

The purpose of this Quality Systems Standard Operating Procedure (QS-SOP) is to support the Quality Assurance Program. The document provides a consolidated reference document for use in training and orientation of employees. This guide will also be a reference tool for more experienced employees. It establishes an approach that can be recommended to sister agencies that monitor Tennessee water or stipulated to members of the regulated community given monitoring requirements in receiving streams. This SOP describes the macroinvertebrate stream survey process and will delineate all steps in the process, including habitat assessments, field collections, sample analysis, data reduction and reporting. This SOP is only intended to describe routine conditions encountered during a macroinvertebrate stream survey.

#### **Federal Statutory Authority**

Federal Water Pollution Control Act (amended through P.L. 106-308, October 13,2000) as Amended by the Clean Water Act of 1977 enacted by Public Law 92-500, October 18, 1972, 86 Stat. 816; 33 U.S.C. 1251 et. seq.

Title III, Sec. 302: Water Quality Related Effluent Limitations

Title III, Sec. 303: Water Quality Standards and Implementation Plans

Title III, Sec. 304: Information and Guidelines

Title III, Sec. 305: Water Quality Inventory

#### **Tennessee Statutory Authority**

Tennessee Water Quality Control Act of 1977 (Acts 1971, ch. 164, § 1; 1977 ch. 366, § 1; T.C.A., § 69-3-101 et seq.

#### **Tennessee Regulatory Authority**

General Water Quality Criteria and the Antidegradation Statement: Rule 1200-4-3

(specifically 1200-4-3-.03(3) j: Biological Integrity and 1200-4-3-.06 Tennessee Antidegradation Statement)

Use Classification for Surface Waters: Rule 1200-4-4

## **I.B METHOD SUMMARY**

This document describes procedures for performing two types of macroinvertebrate surveys approved by the Division of Water Pollution Control for assessing biological integrity of streams. The entire procedure is described including protocols for sample collection, habitat assessment, sample analysis, data reduction and reporting.

Macroinvertebrates are used by the Division as indicator organisms to determine if a stream supports fish and aquatic life. Two types of surveys (biorecons and semi-quantitative single habitat) are used depending on the purpose of the survey.

Biorecons (BR) will be used as a screening or reconnaissance tool to provide a quick evaluation of the relative health of the biological community. The biorecon will be used primarily for general watershed assessments and for determining where more intensive monitoring is needed. This method is not comparable to biocriteria referenced in the Water Quality Standards.

Semi-quantitative single habitat surveys (SQKICK or SQBANK) will be conducted whenever a more defensible and/or definable assessment is needed. This method is directly comparable to biocriteria referenced in the Water Quality Standards. The semi-quantitative biological survey is also preferred in situations where the use attainment status of a stream is not obvious from the results of a biorecon. Tier evaluations under the Antidegradation Policy, enforcement actions and TMDL studies are additional examples of occasions when biorecons may provide inadequate amounts of information and a semi-quantitative sample would be preferable. It is recommended that this method be used by any outside agency or private organization submitting biological data to the Division for review. The semi-quantitative method is required for any individual conducting macroinvertebrate surveys for permit compliance.

Habitat assessments (high gradient and low gradient) are also described in this document. Habitat assessments are to be conducted in conjunction with all types of biological surveys since habitat is often a limiting factor to the complexity of the benthic community. By following this assessment procedure, habitat can either be confirmed or eliminated as a cause of stress to the macroinvertebrate community.

**Macroinvertebrate Survey Quick Field Reference**  
(Minimum tasks to be completed at all biological sampling sites)

1. Upon arrival at site, record lat/long in decimal degrees, verify that sample location is correct.
2. Establish minimum 100 meter reach area (walk bank without disturbing stream).
3. Take field measurements near middle of reach area (minimum DO, temp, pH and conductivity). Record on stream survey field sheet.
4. Collect chemicals (if needed) upstream of area disturbed during field measurements.
5. Collect macroinvertebrate sample (biorecon or SQSH).
6. If biorecon collected and score is ambiguous, collect SQSH if assessment cannot be made based on field observations (see flow chart).
7. Collect periphyton samples if required.
8. Measure flow (only if chemicals were also collected).
9. Measure canopy midstream in middle of riffle where macroinvertebrates are collected or in middle of stream reach if collecting SQBANK or multiple riffles. Estimate average of entire reach. If periphyton are collected at same time, measure midstream at 5 transects instead.
10. Complete stream survey field sheet including stream sketch.
11. Complete habitat assessment field sheet.
12. Take pictures of upstream/downstream sample reach, any habitat problems and potential pollution sources.

## **I.C DEFINITIONS AND ACRONYMS**

*Benthic Community:* Animals living on the bottom of the stream.

*Biocriteria:* Numerical values or narrative expressions that describe the reference biological condition of aquatic communities inhabiting waters of a given designated aquatic life use. Biocriteria are benchmarks for water resources evaluation and management decisions.

*Biometric:* A calculated value representing some aspect of the biological population's structure, function or other measurable characteristic that changes in a predictable way with increased human influence.

*Bioregion:* An ecological subregion, or group of ecological subregions, with similar aquatic macroinvertebrate communities that have been grouped for assessment purposes.

*Ecoregion:* A relatively homogenous area defined by similarity of climate, landform, soil, potential natural vegetation, hydrology, and other ecologically relevant variables. There are eight (Level III) ecoregions in Tennessee.

*Ecological Subregion (or subecoregion):* A smaller area that has been delineated within an ecoregion that has even more homogenous characteristics than does the original ecoregion. There are 25 (Level IV) ecological subregions in Tennessee.

*Ecoregion Reference:* Least impacted waters within an ecoregion that have been monitored to establish a baseline to which alterations of other waters can be compared.

*Habitat:* The instream and riparian features that influence the structure and function of the aquatic community in a stream.

*Headwater stream:* Streams with less than a two square mile drainage area. Typically first or second order.

*Macroinvertebrate:* Animals without backbones that are large enough to be seen by the unaided eye and which can be retained by a U.S. Standard No. 30 sieve (28 meshes/inch, 0.595 mm).

*Reference database:* Biological and chemical data from ecoregion reference sites.

*Riparian Zone:* An area that borders a waterbody (approximately 18 meters wide).

*Stream Order:* Strahler order as determined using 7.5 series topographic maps.

*Watershed:* The area that drains to a particular body of water or common point.

## **I.D HEALTH AND SAFETY WARNINGS**

(Adopted from Klemm et al., 1990)

1. Know how to swim and/or use a PFD when entering the water.
2. Always wear waders with a belt to prevent them from filling with water in case of a fall. In high velocity and high flow streams it is advisable to wear a PFD.
3. Follow Tennessee boating laws and regulations. Information is available through the Tennessee Wildlife Resources Agency. PFD are required when operating a boat.
4. Be vigilant, especially in turbid streams, to avoid broken glass, beaver traps or other hazardous objects that may lie out of sight on the stream bottom. Heavy wading boots should be worn in these situations.
5. Keep first aid supplies in the office, lab and field at all times. Training in basic first aid and cardio-pulmonary resuscitation is strongly recommended.
6. Any person allergic to bee stings or other insect bites should carry needed medications and instruct team mates on how to use in the event of an allergic reaction.
7. Always perform lab work involving ethanol or CMCP-10 in a room containing a properly installed and operating hood.
8. Carry communication equipment in the field in case of emergency.
9. Keep a file in the office that contains emergency contacts and physician's name for each employee.
10. Consider all surface waters potential health hazards due to toxic substances or pathogens and minimize exposure as much as possible. Do not eat, drink, smoke, apply cosmetics or handle contact lenses while collecting samples. Avoid splashing face and clean exposed body parts (face, hands and arms) immediately after contact with these waters. Carry soap and an adequate supply of clean water, disinfectant wipes and/or waterless sanitizer for this purpose.
11. If working in water known or suspected to contain human wastes, get immunized against tetanus, hepatitis, typhoid fever and polio.
12. Try to avoid working alone in the field. When working alone, make sure the supervisor or their designee knows where you are and when you are expected to return. Check in periodically.

13. Material Safety Data Sheets (MSDS) sheets for ethanol and CMCP-10 (if mounting slides) are to be kept in the lab or office. Everyone working with these agents should be familiar with the location and content of the MSDS sheets.
14. Be aware of potentially volatile situations. If possible, obtain permission from land-owners before crossing private property. Have business cards available to leave at residences when appropriate. If approached by someone representing law enforcement, show them your state I.D. and ask to see their I.D. or badge. The Tennessee Highway Patrol can be reached by dialing \*THP (\*847) from your mobile phone.
15. When traveling in a vehicle always wear a seat belt and follow all Tennessee Department of Safety and Motor Vehicle Management rules.
16. In the event of a life threatening emergency, go the nearest hospital. Call for emergency assistance if moving the injured person is likely to inflict further injury. If a non-life threatening injury occurs on the job, seek medical assistance from the authorized state worker's compensation network. A current list of providers may be found on the State Treasurer's homepage under Workers Compensation Provider Directory at [www.tn.gov/treasury](http://www.tn.gov/treasury). Always complete and file an accident report if medical assistance is provided for a work related injury

## **I.E CAUTIONS**

1. Avoid cross contamination of samples. Thoroughly rinse all nets and sieves and inspect for clinging organisms before leaving the sample site. Inspect nets and sieves again immediately before sampling the next site. Use new sample bottles whenever possible, otherwise thoroughly rinse bottles and inspect before use.
2. Avoid sampling bias by following these procedures exactly. Document any deviation.
3. Take care not to over-sample, especially on biorecons. Take care not to undersample (less than 160 organisms) on SQSH samples.
4. Make sure sample site meets ecoregion, drainage area and sample method requirements before comparing to semi-quantitative or biorecon guidelines. Biocriteria metrics used to calculate the TMI can only be applied to SQKICK or SQBANK samples. Never calculate quantitative metrics or apply biocriteria to biorecons.
5. Use the standardized station ID naming protocol for all samples. Check water quality database to make sure a station has not already been established with a different station ID. Notify PAS of any discrepancies. Make sure the station ID is included on all paperwork associated with the sample.
6. Measure stream length from mouth to headwaters. When measuring embayments, measure length of original channel from confluence with the original channel of the main stem. Use GIS (preferred) or map wheel at the 1:2400 (7.5 minute) scale to measure stream miles. When using GIS use the ArcView measuring tool, do not use the Reach File Index or the NHD flowline layer which measures in straight lines. Do not use TDEC on-line assessment map measuring tool as it is inaccurate due to rounding errors. The USGS site <http://water.usgs.gov/osw/streamstats/tennessee.html> may be used.
7. Use 7.5 minute (1:2400) USGS topographic maps or GIS mapping layers to determine Strahler stream order (do not use Gazetteer).
8. To avoid errors, calibrate all meters at the beginning of each day unless overnight travel is required. The meters should minimally be calibrated once a week. Perform a drift check at the end of each day (or on return if overnight travel is required). If the meter calibration is off by more than 0.2 units for pH, temperature or D.O. when measured in mg/L or by more than 10% for conductivity or D.O when measured in % saturation, precede all measurements between the initial calibration and the drift check with an N (questionable data) on the stream survey field sheet and on any Chemical Request Forms (if it is likely that measurements are erroneous record IF for instrument failure). Indicate reason for not recording measurement or for questionable measurements on the stream survey field sheet.
9. If sample request forms have already been submitted, notify the Planning and Standards Section of questionable readings in writing (e-mail or fax).

10. Express all time on a 24-hour (military) clock format.
11. Write all dates in mm/dd/yy or mm/dd/yyyy format.
12. Express all distance measurements in meters, except flow. Flow is expressed in cfs.
13. Make sure to use appropriate units for all field measurements as indicated on the stream survey field sheet.
14. Use GPS to confirm location at site. Record latitude and longitude in decimal degrees.
15. If an error is made in any documentation, draw a single line through the error, so that it is readable and write the correction above. Date and initial the correction.
16. When possible, chemical and semiquantitative (SQSH) macroinvertebrate samples should be collected on the same day (required for CADDIS analysis). If this is not possible, chemical and biological samples should not be separated by more than 4 weeks.
17. Make sure drainage area, sample method and ecoregion drainage are appropriate for comparison to biorecon guidelines or SQSH biocriteria.
18. Check water quality database stations table before assigning station names to make sure a name has not already been assigned to the site by another sampling team or agency. Check station Ids to make verify names follow logical progression from downstream to upstream.
19. Use caution when assessing headwater streams (< 2 square mile drainage) with biorecon guidelines and/or SQSH biocriteria tables. Guidelines are based on a limited number of samples within each bioregion.
20. Take care that additional stream information recorded on the stream survey field sheet does not contradict information provided on the habitat field sheet. This is especially important for sediment and riparian information.

## **I.F INTERFERENCES**

1. Document all deviations from protocol.
2. Semi-quantitative bank samples collected in 65j, 66d, 66e, 66f, 66g, 67f, 67g, 67h, 67i, 68a, 68b, 68c, 69d, 71e, 71f, 71g, 71h, and 74a cannot be compared to biocriteria. If sampling in a non-riffle stream in these regions, an upstream or offsite reference must be collected.
3. Semi-quantitative kick samples collected in 65a, 65b, 65e, 65i, 73a and 74b cannot be compared to biocriteria. An upstream or offsite reference must be collected.
4. Additional samples (of the same habitat) should be collected if needed to ensure 200 organisms were found in the standard collection (document).
5. Avoid sampling in flooded conditions or immediately after a flood.
6. Do not sample if stream is reduced to isolated pools. If stream channel naturally goes dry, only sample if there has been flow for longer than 30 days. Only compare to biocriteria or biocon guidelines for those regions where reference streams routinely went dry (68b, 68c, 69d, and 71i).
7. Flag dissolved oxygen, pH, temperature and conductivity readings with an N (Questionable data) if post-trip drift checks show meter calibrations to be off by more than 0.2 units (or 10% for conductivity).
8. Organisms that are marked verified on the Tennessee taxa list (Appendix C) must be sent to the state lab for verification and inclusion in the statewide reference collection. After in-house confirmation, the state lab will send any new taxon to a qualified expert for verification (Appendix D).
9. Sampling stations should be located in areas where the benthic community is not influenced by atypical conditions, such as those created by bridges or dams, unless judging the effects of atypical conditions is a component of the study objectives.

## **I.G PERSONNEL QUALIFICATIONS**

Tennessee Civil Service Titles: Biologist or Environmental Specialist (state employees only).  
For the purpose of this report, both position titles will be referred to as biologist.

Minimum Education Requirements: B.S. in a biological science. Coursework in stream ecology and macroinvertebrate taxonomy is desirable. A graduate level degree in stream ecology, aquatic biology or similar field is preferable.

Minimum experience: one year (specific class-work involving biological stream surveys and macroinvertebrate taxonomy can be substituted for experience)

Expertise: Macroinvertebrate taxonomy (must be able to consistently pass quality control checks), computation of basic statistics, use of standard water quality monitoring meters, habitat evaluations and general water quality assessments.

Training: Protocols outlined in this SOP  
Quality System Requirements  
Quality Assurance Project Plan for 106 monitoring

## **I.H. EQUIPMENT AND SUPPLIES**

Prior to any sampling trip, gather and inspect all necessary gear. Replace or repair any damaged equipment. Calibrate all meters the morning of the sampling trip with a drift check at the end of the day (or the end of the trip for overnight stays). Upon return from a trip, take care of any equipment repairs or replacements immediately. Necessary equipment will vary per project, but the following is a standardized list.

### **Field Equipment**

Waders  
Forceps  
Ethanol  
External sample tags  
Internal sample tags  
Habitat Assessment Field Sheet (High gradient for riffles, Low gradient for glide-pool)  
Stream Survey Field Sheet  
Biorecon Field Sheet (Biorecons only)  
Biological Analysis Request Form (for Chain of Custody and/or samples sent to lab)  
Topographic maps (USGS quadrangle maps) may also be referred to as topos or quads.  
Tennessee Atlas and Gazetteer  
½ gallon wide mouth plastic sample bottles for Semi-Quantitative samples  
Small wide mouth plastic bottles for biorecons  
Calibrated GPS unit  
Calibrated Dissolved Oxygen meter and replacement membrane kit  
Calibrated pH meter  
Calibrated conductivity meter  
Calibrated temperature meter or thermometer in °C  
Spare batteries for all electronic equipment  
Camera (preferably digital) with memory cards or film  
Triangular dip net with 500-micron mesh (Biorecons and SQBANK samples only)  
One meter square kick net with 500 micron mesh (SQKICK samples only)  
Rectangular net (18") with 500 micron mesh (SQKICK in small streams only)  
Sieve bucket with 500 micron mesh  
White enamel or plastic pans for sorting debris (biorecons only)  
Magnifying lens  
Waterproof marking pens (Sharpies), pencils and black ballpoint ink pens (not roller-ball)  
Flashlights  
Duct Tape  
First Aid Kit  
Time keeping device  
Spherical densiometer (for canopy measurements)  
Map Wheel or GIS capability (to calculate stream miles to assign station ID in field if needed)  
Cell phone desirable (or other method for contacting help in emergency)

## **Laboratory Equipment**

The following equipment is needed to perform sample analysis (semi-quantitative samples only).

Dissecting Microscope  
Compound Microscope  
Jewelers Forceps  
Petri dish  
Microscope slides  
Round 12 mm coverslips  
Square 22 mm coverslips  
Gridded Tray with subsampling insert  
Small Gridded dish (36 grids)  
Ethanol  
CMCP-10 or equivalent permanent mounting media  
Random number jar  
Taxonomic Bench Sheet  
Turkey baster (or equivalent suction device)  
Transfer pipette (or equivalent suction device)  
Slide storage box  
Glass vials with rubber or Teflon line lid (for reference specimens)

The following equipment is needed for laboratory confirmation of biorecons

Dissecting Microscope  
Jewelers Forceps  
Petri dish  
Ethanol  
Glass vials with rubber or Teflon line lid for reference specimens

## **Sample container and Ethanol Acquisition**

Sample containers and ethanol are to be obtained through the Tennessee Department of Health Environmental Laboratory in Nashville.

Supplies must be requested at least two weeks prior to the anticipated date they will be needed (preferably one month)

| Item                                 | Old Inventory No. | Edison Number |
|--------------------------------------|-------------------|---------------|
| SQSH Jar 1/2 gal                     | 200-08210         | 1000109388    |
| 1 oz wm bottle (Biorecon collection) | 200-0190          | 1000109082    |
| Alcohol Ethyl                        | 400-0700          | 1000109487    |

## I.I PROCEDURES

### Protocol A - Selection of Survey Type and Station Location

#### Biologist or Environmental Specialist from EFO Central Office Coordinator

1. Determine biological sampling needs.

The central office will coordinate biological sampling needs with the environmental field offices. The location and type of scheduled biological assessments will be included in the annual water quality monitoring workplan. Additional biological assessments may be conducted as needed.

Biological sampling will generally follow the watershed cycle. When developing the monitoring workplan within the targeted watershed, macroinvertebrate samples should be collected with the following priority:

- a. Ecoregion reference sites (ECO and FECO).
- b. Sites on the 303(d) list for Fish and Aquatic Life
- c. TMDL or other sites where nutrients samples are going to be collected (ideally macroinvertebrates should be collected on same day as chemicals at least once to maximize versatility and statistical power of data). It should be noted that nutrient impairment cannot be evaluated in the absence of a macroinvertebrate sample unless other biological evidence, such as excessive algal growth is documented.
- d. Sites below point source discharges in wadeable streams **when in-stream biological surveys are not required in discharge or stormwater permits**. Location of point source discharges and permit requirements can be accessed through Waterlog. To download a spreadsheet by watershed go to the WPC reports, permits by watershed cycle, interactive format. Biological surveys submitted by permitted discharges are available in SQSH WPC new and other agency table of Water Quality Database provided to field offices monthly.
- e. Sites below ARAP activities in wadeable streams that have been completed since the last watershed cycle where biological impairment is suspected. Emphasis should be placed unpermitted activities, violations and those that are large scale or where there are a dense concentration of smaller alterations. Waterlog can be accessed to get information on ARAP activities. To download a spreadsheet by watershed go to the WPC reports, permits by watershed cycle, interactive format. Examples of ARAP activities where downstream monitoring may be warranted include commercial dredging, stream

relocations, impoundments, concentrated or large scale water withdrawals and major road construction.

- f. Stream reaches suspected of non-point source (for example large scale development, cluster of stormwater permits, increase of more than 10% impervious surface or other potential problems).
  - g. Sites where the last sample was ambiguous (collect SQSH at these).
  - h. Previously assessed segments. (Note that a single site per assessed segment is adequate if assessment was supporting and no changes are evident.)
  - i. Unassessed reaches (fish and aquatic life) especially in third order or larger streams or in headwaters that have human disturbance and downstream reaches are not impaired.
2. The type of macroinvertebrate sample will be determined based on the type of assessment needed. In general biorecons will be used for routine watershed assessments and screening while SQSH will be used when a more defensible assessment is needed and for clarification of ambiguous biorecons. It can also be used to confirm biorecons where score does not, in the opinion of the biologist, reflect true stream conditions. (For example richness is high but abundance appears low). Figures 1-4 provide guidelines for determining what type of biological sample is most appropriate.

If chemical and SQSH samples are to be collected from the same site, it is desirable that at least one chemical sample be collected on the same date to provide maximum statistical power and make data useful for other purposes such as criteria development, biometric calibration and correlation analysis. If it is not possible to collect the same day, chemical and SQSH samples should be collected as close as possible (for example the same week or at least the same month). It is required for samples to be collected the same day when conducting CADDIS analysis.

- a. Ecoregion reference sites (ECO and FECO) – Biorecon and SQSH (Figure 1).
- b. NPDES permit compliance, enforcement, nutrient TMDL, Pre/post BMP, Pre/post ARAP, potential ETW, CADDIS – SQSH (Figure 2).
- c. 303(d) list – SQSH or Biorecon (Figure 3).
- d. Watershed Assessment – SQSH or Biorecon (Figure 4).

It is recommended that biorecons not be used in ecoregion 73 since the intolerant richness metric is not useable.

## Biological Sample Decision Making Flowcharts

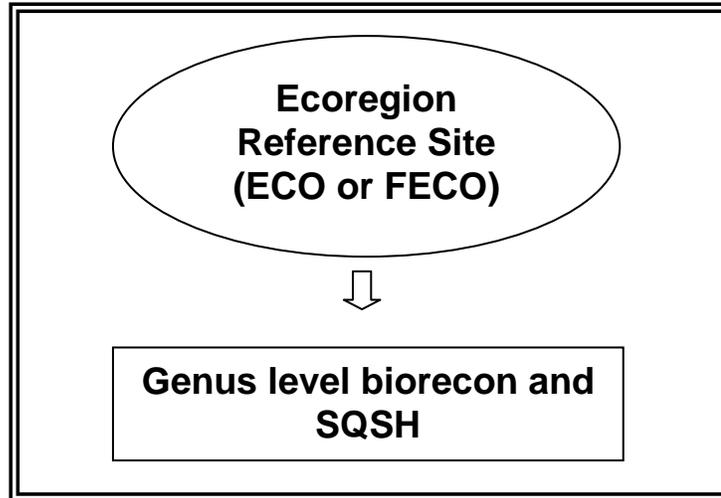

Figure 1: Biological sample decision making chart for ecoregion reference sites.

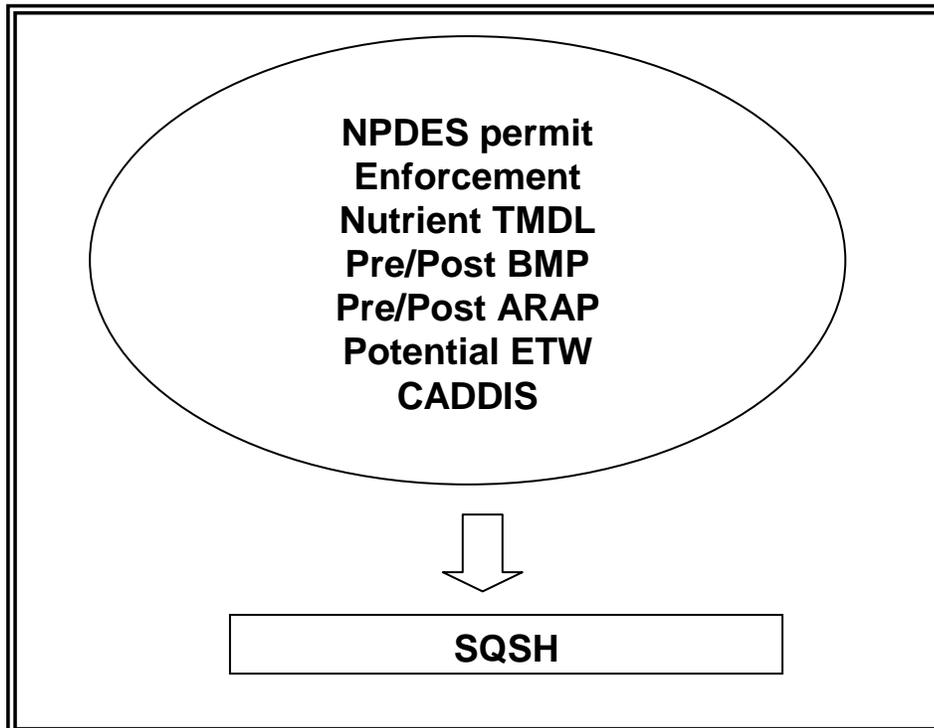

Figure 2: Biological sample decision making chart for NPDES, enforcement, nutrient TMDL, BMP and potential ETW sites.

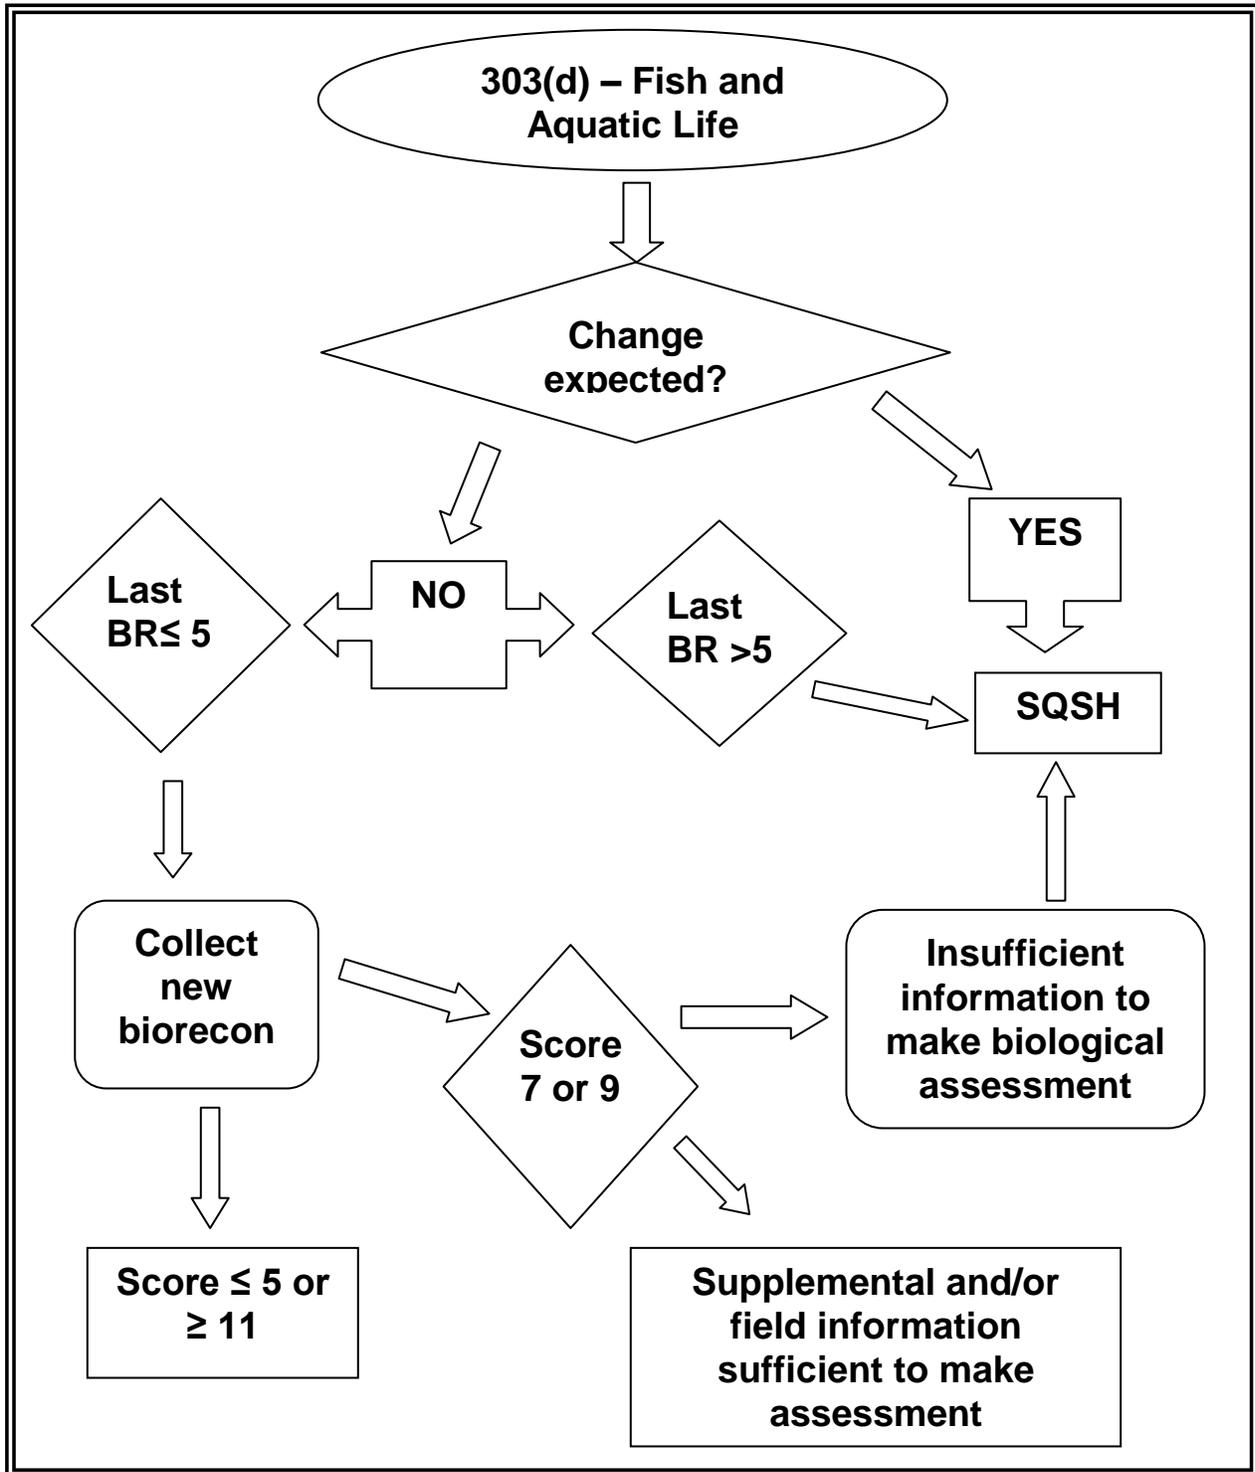

Figure 3: Biological sample decision making chart for 303(d) listed sites.

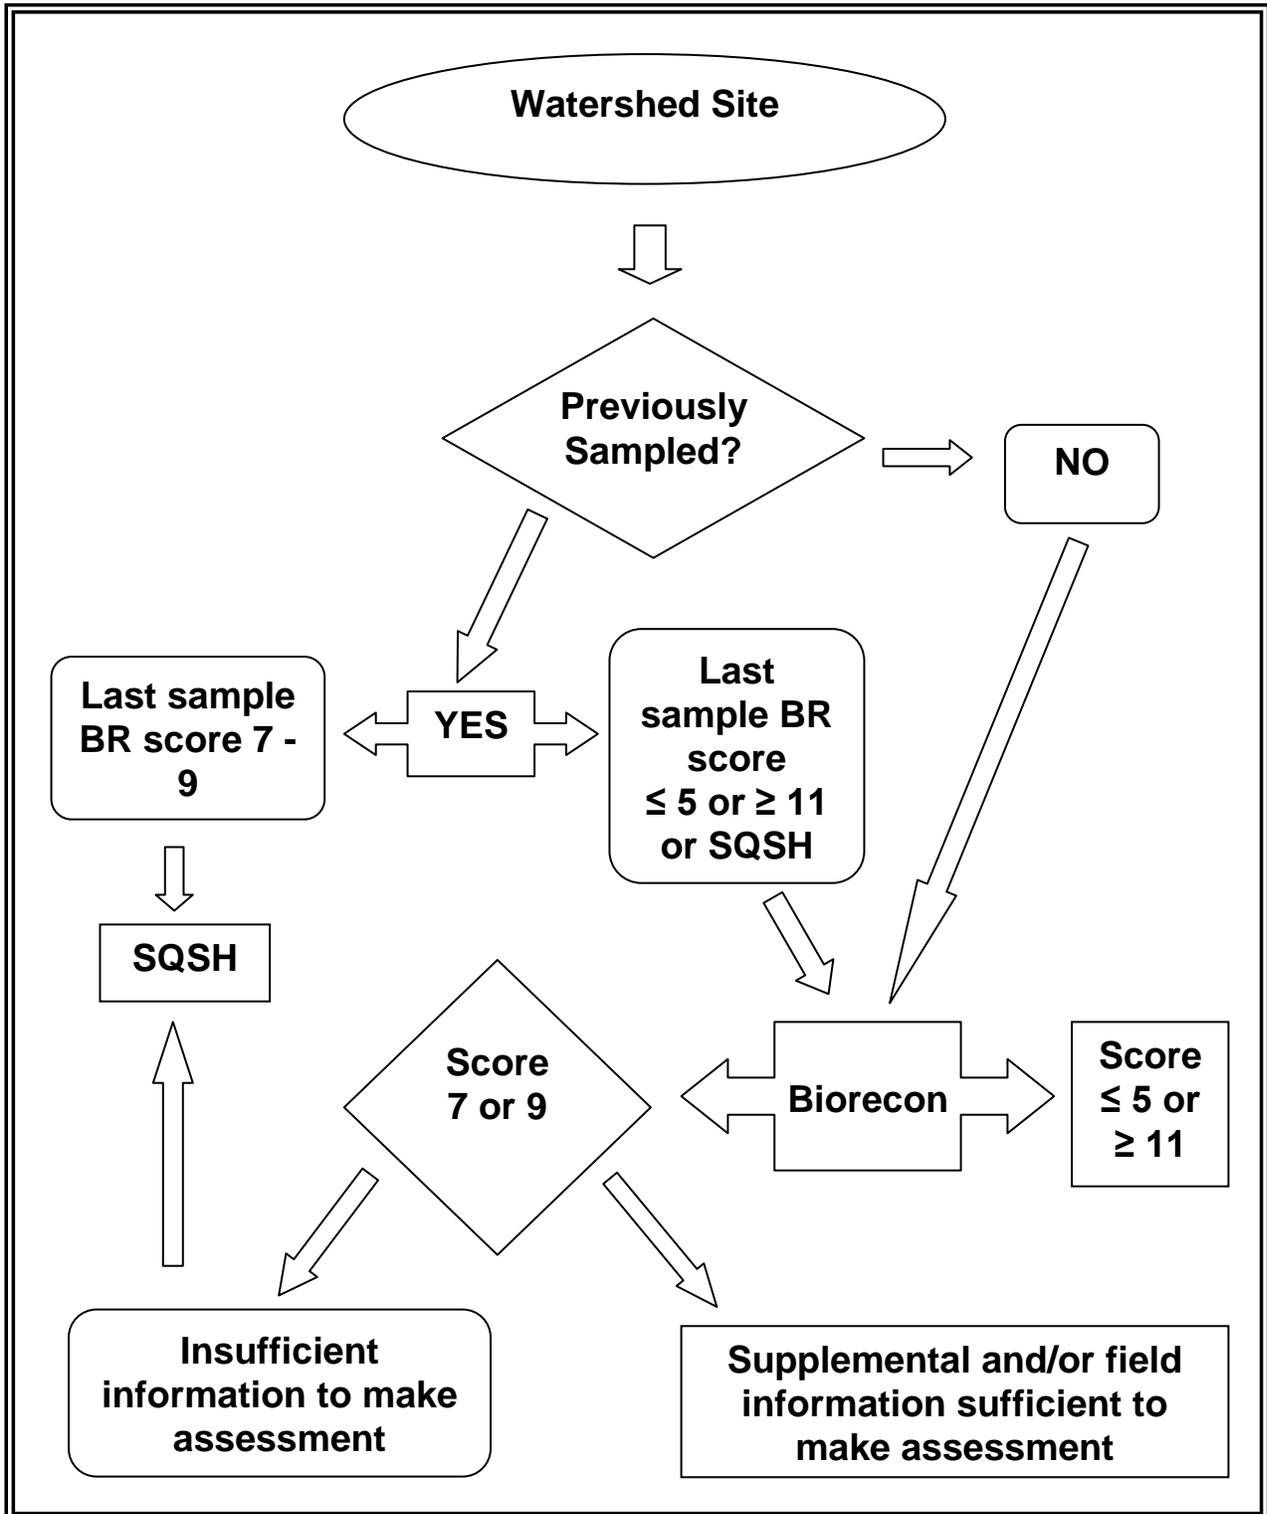

Figure 4: Biological sample decision making chart for watershed sites.

3. Select sites.

Site selection is dependent on the study objectives. After determining the specific objectives of the study and clearly defining what information is needed, select sampling sites on specific reaches of the stream. Reconnaissance of the waterway is very important. Note possible sources of pollution, access points, substrate types, habitat, flow characteristics, and other physical characteristics that will need to be considered in selecting the sampling sites. Although the number and location of sampling stations will vary with each individual study, the following basic rules should be applied:

- a. Determine whether an upstream or watershed **reference site** is needed or if the study site can be compared to biocriteria (Appendix A) or biorecon guidelines (Tables 4 and 5) derived from the ecoregion reference database. In order to compare to biocriteria, the watershed upstream of the test site must:
  1. Be at least 80% within the specified bioregion
  2. Be of the appropriate upstream drainage area
  3. Be collected using the collection method designated for that bioregion (SQKICK or SQBANK).

This information can be found in Appendix A. Compare all appropriate semi-quantitative samples to biocriteria. Depending on study purposes or if the study stream does not meet requirements for the reference database, an upstream sample or an appropriate watershed reference may need to be collected. Instructions for comparing data to an alternate reference are provided in Protocol K.

Compare biorecons on streams whose upstream drainage is at least 80% within a bioregion to guidelines developed from the ecoregion reference database (Tables 4 and 5). If the test stream crosses multiple bioregions upstream of the test site, select an appropriate upstream or watershed reference. (An alternative is to compare the site to guidelines for each appropriate bioregion, however if assessments differ another reference must be used). Instructions for comparing data to an alternate reference are provided in Protocol F.

- b. For watershed screenings, locate sites near the mouth of each tributary. If impairment is observed, locate additional sites upstream of the impaired stream reach to try to define how far the impairment extends and locate potential sources.
- c. For monitoring point source pollution, establish a station downstream of the source of pollution in the stream after mixing has occurred. If complete mixing of the discharge does not occur immediately, left bank, mid-channel and right bank stations may need to be established to determine the extent of possible impact. Establish stations at various distances downstream from the discharge. Space the collecting stations exponentially farther apart going downstream from the pollution source to determine the extent of the

recovery zone. For intermittent discharges, sampling should be within thirty days of last discharge. An additional site should be located upstream of the discharge point to help identify influences associated with the discharge.

- d. For site specific sampling, locations immediately above, or below the confluence of two streams, or immediately below point/nonpoint source discharges, should be avoided if mixing does not immediately occur. Unless the stream is extremely small or extremely turbulent, an in-flow will usually hug the stream bank with little lateral mixing for some distance. This may result in two very different biological populations and an inaccurate assessment of stream conditions. This can be avoided by sampling after mixing has occurred.
- e. All sampling stations under comparison during a study should have similar habitat unless the object of the study is to determine the effects of habitat degradation.
- f. Sampling stations for macroinvertebrates should be located within the same reach (200 meters or yards) of where sampling for chemical and physical parameters will be located. If the macroinvertebrates are collected more than 200 meters from the chemical sampling, consider it a separate station and assign it a different station ID number unless there are no tribs, discharges, construction, agriculture, road crossings or other activities that would influence the stream between the chemical and biological sampling points.
- g. Sampling stations should be located in areas where the benthic community is not influenced by atypical conditions, such as those created by bridges or dams unless judging the effects of atypical conditions is a component of the study objectives.
- h. Ecoregion reference sites may be relocated upstream if localized disturbance is observed during sampling (for example beaver activity, riparian disturbance, 4-wheel activity, dredging etc.)
- i. Stream must have had flow for a minimum of 30 days prior to sampling. Avoid habitats that may not have been submerged for 30 days, isolated pools or stagnant water.

## **Protocol B – Assigning Station ID**

### **Biologist/Environmental Specialist**

Assign station IDs to each site using the following protocol. The station ID will be used to identify the sample and must be included on all associated paperwork, results, tags etc. This number is to be used to identify this site every time it is sampled for any parameter (benthic, fish, bacteria, chemical). If new stations are set up that will also have chemical or bacteriological monitoring, send the new station information to Planning and Standards as soon as the station location is finalized and before the lab sends results (Usually 30 days). Minimally station information should include station ID, latitude and longitude (in decimal degrees), HUC, ecoregion, stream order and specific location information (such as road crossing) that can be located on a map. If only biological samples will be collected, complete all header information on the stream survey field sheet and send with biological data packet to lab (SQSH) or PAS (biorecon). If the stream is first or second order, drainage area must be indicated.

**It is very important that station IDs are assigned consistently with the same location always assigned the same ID regardless of the sample collection type, purpose, samplers or year.**

1. **Before assigning a new station ID, check the “current stations” table in the Water Quality Monitoring database to make sure a number hasn’t already been assigned to that site.** Even if the site has not been collected before by the EFO, a station ID may have already been assigned based on other agency data (NPDES instream sampling, ARAP, special projects, TVA etc.). Do not assume that a station does not exist because it has not been collected by the EFO. It is very important that all data from a single location be given the same station ID to facilitate assessments based on all available information. Contact the Planning and Standards section if there is any question or if there are naming errors associated with existing stations.

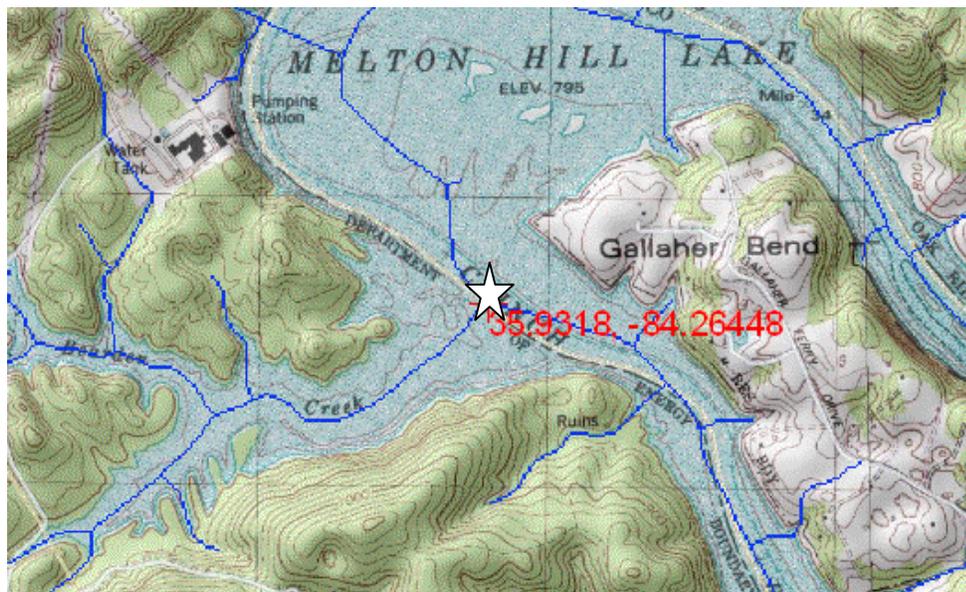

Unless the sites are located upstream and downstream of a point source discharge, tributary confluence or some other factor that would affect the stream, stations collected within 200 meters of each other are considered the same site. (So, if chemical samples were taken off the bridge and biological samples were collected up to 200 meters upstream, they are still the same station.)

Chemical and biological stations collected more than 200 meters apart can still be considered the same station if there are no tributaries, discharges, construction, agriculture, road crossing or other activities that would influence the stream between sampling points. **It is very important for biological and chemical samplers to coordinate naming of station locations to avoid confusion.**

2. **The official stream name is the one found on the USGS 7.5 minute topographic map or equivalent GIS layer.** Do not use other sources such as gazetteer, TDOT bridge signs or local names, which may differ.
3. **It is also important that river miles used in the station ID are measured as accurately as possible and correspond to the latitude and longitude for easy comparison between multiple stations on the same waterbody.** Only use GIS (preferred), map wheel or <http://water.usgs.gov/osw/streamstats/tennessee.html> to measure stream miles. Always use the 1:2400 scale. When using GIS use the ArcView measuring tool, do not use the NHD flowline layer or Reach File Index. Do not use TDEC on-line assessment map measuring tool as it is not accurate due to rounding.

**When measuring river miles for streams that enter an embayment, begin measurement from the confluence with the original channel of the main stem (not from where the stream becomes an embayment).** For example, in Figure 5, river mile 0 for Bearden Creek would start at the confluence with the original channel of the Clinch River as marked on the topo within Melton Hill Lake. Follow the original stream channel line if marked on the topo (do not use “poly lines”). If the original stream channel is not marked on the topo, straight lines may be used through the embayment area.

**If there are other stations located on the same stream, make sure the assigned river miles are appropriately upstream or downstream of existing stations.** If errors are discovered on existing stations, contact PAS to have the stations reassigned.

**Figure 5: Start of river mile for measuring creeks within embayment areas.**

The only exception to the naming scheme is sites that have been designated as Ecoregion or headwater reference sites. These sites are always identified with their ECO or FECO designation no matter what the purpose of sampling. If new ecoregion reference sites are added, contact Planning and Standards (PAS) to determine the appropriate station name.

#### 4. Named streams/rivers

If a number does not already exist for the site, create an identification number. All letters in the station name are capitalized.

- a. The first five digits will be the first five letters of the stream name (capitalized). If the stream name has more than one word, use the first letter of each word finishing out the five letters with the last word. For example, South Fork Forked Deer River would be SFFDE. Do not use the words River, Creek Branch etc. (Fork is only used if the stream is also designated river, creek, branch etc.) For example, Dry Fork would be DRY but Dry Fork Creek would be DFORK. **The stream name will be one designated on the 24 scale USGS topographical map or GIS layer. (Do not use the Gazetteer, local name, TDOT signs etc.).**
- b. The next five characters designate the river mile. This will be written as three whole numbers, a decimal and a tenth space. For example, river mile 1.2 would be written as 001.2. Do not add zeros to make a short stream name longer. It is very important that the river mile be determined as accurately as possible (see number 3 above).
- c. The last two characters designate the county (or state if not in Tennessee). Use the County Identification table in Appendix B to determine the appropriate county designation. The county is expressed with two letters; do not use the numeric state code. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example 1: A station located at river mile 1.5 on Puncheoncamp Creek in Greene County would be PUNCH001.5GE

Example 2: A station located at river mile 25 on the North Fork Forked Deer River in Gibson County would be NFFDE025.0GI.

Example 3: A station that is located in Kentucky at river mile 15.2 of Spring Creek would be SPRIN015.2\_KY.

## 5. Unnamed Streams/Tributaries.

Check a 24k scale topographic map (hardcopy or GIS) layer to see if the unnamed stream is within a named geographical features such as a cove, hollow, gulf, gulch or valley.

### a. For streams that are not within a named geographical feature:

- (1) Use the first five letters of the receiving stream the tributary enters.
- (2) Use a 5-character stream mile to indicate where the tributary enters the main stem (whole number, decimal and tenth for example river mile 114.6 would be entered 114.6).
- (3) Use the letter T to indicate a tributary.
- (4) Use the river mile of the unnamed tributary where the station is located.
- (5) Use the two letter county abbreviation from Appendix B. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

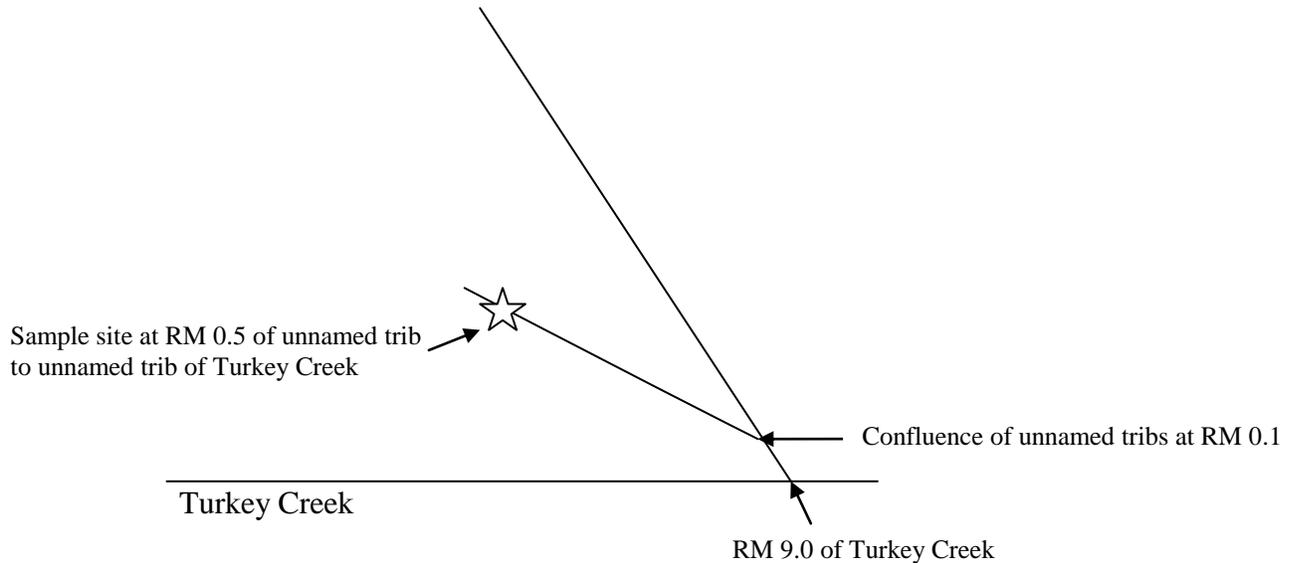

Example 1: A station located at river mile 0.2 on an unnamed tributary that entered the Harpeth River at river mile 114.6 in Williamson County would be HARPE114.6T0.2WI.

Example 2: A second station at river mile 0.3 on the same trib would be HARPE114.6T0.3WI.

Example 3: A station located at river mile 5.5 on a different unnamed tributary which entered the Harpeth River at mile 115.0 in Williamson County would be HARPE115.0T5.5WI.

- (6) When naming an unnamed tributary to an unnamed tributary, start at the named stream (mainstem) and work upstream to the sampling point.
  - (a) Record the first five letters of the mainstem (named stream).
  - (b) Record the river mile where the first unnamed tributary enters the main stem followed by a T.
  - (c) Record the river mile where the second unnamed tributary enters the first one, followed by a T.
  - (d) Record the river mile where the station is located, followed by the county designation.

Example: A station at river mile 0.5 on an unnamed tributary that flows into a second unnamed tributary at river mile 0.1 which, in turn flows into Turkey Creek at river mile 9.0 in Gibson County would be TURKE9.0T0.1T0.5GI (Figure 6).

**Figure 6: Naming scheme for stations located on unnamed tributaries to unnamed tributaries. Station ID TURKE9.0T0.1T0.5GI**

**b. For streams that are within a named geographical feature:**

- (1) The first five digits will be the first five letters of the name of the geographical feature (capitalized). If the feature name has more than one word, use the first letter of each word finishing out the five letters with the last word. Do not use the words Cove, Hollow, Gulch, Gulf, or Valley. If the feature name has fewer than five letters use the entire name.
- (2) Add the underscore\_G to indicate that the station is named after a geographical feature and not a named stream. Streams with “\_G” will be the main branch running through the feature.
- (3) The next three characters designate the miles upstream from the nearest named stream or waterbody. This will be written as one whole number, a decimal and a tenth space. For example, river mile 1.2 would be written as 1.2. If the stream is an unnamed tributary to the main branch (\_G streams), the miles will be measured upstream from the main branch instead of the nearest named stream or waterbody (see example 3).

- (4) Use the two letter county or state abbreviation from Appendix A. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example 1: A station that is in Shingle Mill Hollow in Marion County and is 0.3 miles upstream from Nickajack Reservoir, which is the closest named waterbody would be SMILL\_G0.3MI.

Example 2: A station that is located on an unnamed main branch in Cave Cove in Marion County that is 0.4 miles upstream of the nearest named stream would be CAVE\_G0.4MI.

Example 3: A station at river mile 0.2 on an unnamed tributary that enters main branch in Cave Cove at river mile 1.0 would be CAVE1.0G0.2MI.

## 6. Wetlands

### a. For named wetlands

- (1) Use the first five letters of the wetland name if one word – if more than one word use the first letter of each word plus as many letters are needed in the last word to get five total letters (see 2.a).
- (2) Add underscore\_W.
- (3) Use a 3-character stream mile including one whole number, the decimal and a tenth space. For example river mile 1.2 would be written as 1.2.
- (4) Use the two letter county or state abbreviation from Appendix A. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example 1: A station located at DUCK wetland would be DUCK\_W1.2CH.

Example 2: A station located at BLACK HORSE wetland would be BHORS\_W1.2CH.

### b. For unnamed wetlands with an associated stream

- (1) Use the first five letters of the stream associated with the wetland if one word – if more than one word use the first letter of each word up to five letters (see 2. a.).
- (2) Add underscore\_W
- (3) Use a 3-character stream mile including one whole number, the decimal and a tenth space. For example river mile 1.2 would be written as 1.2.

- (4) Use the two letter county or state abbreviation from Appendix A. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example: A wetland associated with a stream Clear Creek would be CLEAR\_W1.2SM.

**c. For isolated unnamed wetlands with no stream associated with it, use the name associated with the ARAP permit request.**

- (1) Use the first five letters of the company associated with the wetland, - if more than one word use the first letter of each word up to five letters.
- (2) Add underscore\_W.
- (3) Use a 3-character stream mile including one whole number, the decimal and a tenth space. For example river mile 1.2 would be written 1.2.
- (4) Use the two letter county or state abbreviation from Appendix A. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example: Company name Boones Farm BFARM\_W1.2CO

**7. Sinking streams (with no clear channel or surface flow to main stem – use standard naming scheme for streams with clear channel or that resurface)**

- a. Use the first five letters of the stream name if one word – if more than one word use the first letter of each word up to five letters. For unnamed sinking streams or if the receiving stream is unclear use the first five letters of the closest mapped feature.
- b. Add underscore \_S.
- c. Use a 3-character stream mile including one whole number, the decimal and a tenth space (use additional characters as needed if the stream mile is greater than 9.9). Start mileage from the point where the stream disappears (if the stream resurfaces downstream and it is clearly the same stream, estimate the distance between surface points).
- d. Use the two letter county or state abbreviation from Appendix A. If the station is in another state, add an underscore \_ before the two letter state abbreviation.

Example 1. A station located at river mile 1.2 on Dry Creek would be DRY\_S1.2CU.

Example 2. A station located at river mile 11.2 on Stinky Cow Creek would be SCOW\_S11.2CU.

Example 3. An unnamed sinking stream station located on Crane Top Ridge with no clear flow pattern would be CTOP\_S1.2FR

## **8. Reservoirs (man-made lakes)**

- a. Assign the first 5 letters of the impounded stream (or embayment).
- b. Use a 5 character stream mile if the sample is collected near the river channel. If the sample is collected near the right or left bank (such as at a boat dock) use a 4 character stream mile and the letter L or R to designate the right or left descending shore.
- c. Use the appropriate 2 letter county or state abbreviation from Appendix A. Add an underscore \_ before the two letter state abbreviation for stations in another state. For example, a station that was collected from a boat on Fishing Lake which dams Otter Creek in Anderson County would be OTTER012.3AN. If the station was collected off a dock near the left descending shore the station ID would be OTTER12.3LAN.

In the site description include the reservoir name as well as location for clarification (for example Otter Lake near boat dock)

## **9. Natural Lakes**

- a. Use the first 5 digits of the lake's name.
- b. Using an S to designate station and a two digit whole number, assign the next available station ID. For example if station IDs 1 through 4 already exist on that lake from previous studies (check the water quality database) then use station ID 5. This would be designated S05.
- c. Use the appropriate 2 letter county or state abbreviation from Appendix A. Add an underscore \_ before the two letter state abbreviation for stations in another state.

For example, a new station located on Reelfoot Lake in Obion County would be REELFS11OB.

**Protocol C – Field Parameters**

Adapted from U.S. Environmental Protection Agency. 2002

**BIOLOGIST/ENVIRONMENTAL SPECIALIST**

**Dissolved Oxygen, pH, temperature and conductivity measurements are to be recorded at each biological monitoring station every time the site is sampled.** Field parameters are to be recorded on the stream survey field sheet (Protocol E). Multi-probe or individual meters meeting the following specifications can be used.

Measure dissolved oxygen, pH, temperature and conductivity before biological samples are collected. (If also collecting chemical or bacteriological samples, measure field parameters after these samples are collected and before flow is measured). Place the probe upstream of where surface water samples were collected. Allow sensors to equilibrate before recording measurements. Document all measurements including duplicates on the stream survey field sheet.

Label all meters as property of the State of Tennessee, Department of Environment and Conservation. Assign each meter a distinct identifying designation, (i.e. letter or a portion of the serial number) for calibration, maintenance, and deployment records. Mark each meter with this designation. Record the meter’s ID number on the Stream Survey Field Sheet. Multi-probe or individual meters meeting the following minimum specifications may be used (Table 1). Beyond following the instructions in this SOP for calibrating, maintenance, and logging procedures, it is also recommended to refer to manufacturer’s instructions.

**Table 1: Water Quality Probe Minimum Specifications**

| Parameter             | Range                 | Accuracy          | Resolution |
|-----------------------|-----------------------|-------------------|------------|
| Temperature           | -5 °C to 45 °C        | +/- 0.20 °C       | 0.1 °C     |
| Specific Conductivity | 0 to 100,000*umhos/cm | +/- 1% of reading | 4 digits   |
| pH                    | 2 to 12 units         | +/- 0.2 units     | 0.01 units |
| Dissolved Oxygen      | 0 to 20 mg/L          | +/- 0.2 mg/L      | 0.01 mg/L  |

\* Areas of mining or other high conductivity/low pH may need a higher range.

- 1. Calibrate Meter(s)** – Meters only need to be calibrated if they are going to be used that week. At the beginning of each week or day or within 24 hours of use, calibrate meter(s) for all parameters that will be measured, following the manufacturer’s instructions. Conductivity and pH probes are calibrated weekly with a drift check performed daily upon return (or at the end of the sampling period if overnight travel is involved). The drift check can be performed the next morning if time is a factor. The probes must be recalibrated when the drift check is out of the acceptable range, otherwise calibrating these probes once a week is acceptable. A drift check should be performed weekly for temperature. DO probes are to be calibrated each morning of use and at each site where necessary (see # 2). Drift

checks for DO probes are not necessary if the meter was recalibrated in the field. If probes are factory calibrated, check readings against the appropriate standards to ensure the calibration is still accurate. Maintain calibration SOPs for each type and/or brand of meter. Keep all calibration records in a backed up digital format (preferred) or bound logbook (Figure 7). Include the date, meter designation, project name/number, initials of calibrator, parameter, standards used, meter reading, and adjustments. Also, record routine maintenance and repairs in the logbook. Some probes must be sent to the manufacturer for calibration. Other probes must be replaced when they no longer maintain their calibration. In these cases, refer to manufacturer's instructions.

To check the calibration of the temperature probe place an ASTM thermometer in a container of room temperature water large enough to submerge the temperature probe. Place the meter in the water bath and allow it to equilibrate then compare the probe's reading to the thermometer's reading and mathematically adjust the probe's temperature as necessary. Coordinate with TDH laboratory to include the ASTM thermometer in their annual thermometer calibration check against the ASTM certified thermometer. Record this information in the calibration log.

| Date   | Meter | Project     | Init. | Parameter    | Standard | Reading | Adj | Comments            |
|--------|-------|-------------|-------|--------------|----------|---------|-----|---------------------|
| 3/6/02 | YSI-A | Davis<br>Ck | JEB   | Conductivity | 142      | 120     | 142 | Cleaned<br>contacts |
| 3/6/02 | YSI-A | Davis<br>Ck | JEB   | Conductivity | 142      | 140     | NA  | Drift Check         |
|        |       |             |       |              |          |         |     |                     |

**Figure 7: Meter Calibration Log**

- 2. Calibrate DO Probe** – The DO probe must be calibrated using either Winkler Titration (mg/l) or air calibration (% saturation) each morning prior to use. Most probes automatically compensate for temperature changes. Some probes also automatically compensate for pressure changes. An ASTM r calibrated thermometer and/or a handheld barometer must be carried in the field if the probe does not compensate for temperature and/or pressure changes. It is only necessary to recalibrate the probe at sites where there is a significant elevation, pressure or temperature change and the meter does not automatically compensate. A significant change in elevation is 1000 feet. A significant change in pressure is  $\pm 20$  mm Hg (higher or lower) or when a storm front comes through the area. A significant change in temperature includes any  $\pm 5^{\circ}\text{C}$  change in temperature (higher or lower). If the DO probe is air calibrated, changes in pressure do affect concentration readings. Record the air calibration at the site in a calibration log in the field to the specified resolution in Table 1.

- 3. Probe Placement** – Ideally, measure water parameters after collecting chemical and bacteriological samples and before measuring flow or collecting other samples (i.e. macroinvertebrate, periphyton). Turn on the meter(s) and if there is a DO stirrer, be sure it is activated. Carefully place the meter(s) in the thalweg upstream of the chemical and bacteriological sampling area. Suspend the probe(s) in the water column so it does not touch the bottom. If the water is too shallow to suspend the meter(s), carefully lay it on its side on firm substrate (preferably rock). Do not allow the probe(s) to sink into soft substrate.

Stand downstream of the probe, being careful not to disturb the substrate in the area of the probe(s). Allow enough time for each reading to stabilize before it is recorded. Depending on the meter, it may take a couple of minutes for dissolved oxygen to equilibrate. Record initial readings in the field notebook or the stream survey field sheet to the specified resolution (Table 9).

- 4. Duplicate Readings** - Take duplicate measurements at each site. If time is a constraint (short sample holding times or daylight), duplicate readings may be reduced to the first and last site each day. To take a duplicate measurement, lift the probe completely out of the water, wait for the readings to change then return it to the original location or slightly upstream if the sediment was disturbed. Allow the meter to equilibrate before recording readings. If the readings are off by more than 0.2 units for pH, temperature, and DO in mg/L or off by more than 10% for specific conductivity, repeat the procedure until reproducible results are obtained. Record all readings on the stream survey field sheet. All results are to be recorded to the resolution specified in Table 1. Rinse the probes with tap water after use at each site to avoid contamination.
- 5. Record Field Parameters** – Document the field measurements on the stream survey field sheet. Specific conductivity must be recorded in umhos/cm or uS/cm, dissolved oxygen in ppm (mg/l), and temperature in °C.
- 6. Drift Check** – Without post-calibration checks, the accuracy of the water parameter measurements cannot be demonstrated. At the EFO lab, perform a drift check on each meter at the end of the day (or at the end of the trip on multiple night trips) and record results in the logbook (Figure 5). Drift checks can be done in the field as long as you have the proper equipment. To check that the probes have maintained their calibration for pH and conductivity, compare the probe's readings against the appropriate pH, and conductivity standards. Adjust calibration if the probe is going to be used again that week. If the meter's calibration is off by more than 0.2 for pH or more than 10% for conductivity, all readings between the initial calibration and the drift check must be marked as questionable (N). To check that the probes have maintained their calibration for temperature, compare the probe's readings against a standard ASTM thermometer. If the meter's calibration is off by more than 0.2, all the readings between the initial calibration and the drift check must be marked as questionable (N). When the DO probe has been air calibrated in the field due to pressure, elevation or temperature changes, a drift check is unnecessary at the end of the day. If the

DO probe was not re-calibrated since leaving the base office, a drift check (Winkler or air calibration) should be performed at the end of the day. If the meter's calibration is off by more than 0.2 mg/L (Winkler) or 10% (air), all readings between the initial calibration and the drift check must be marked as questionable (N). On stream survey field sheets precede all questionable readings with an "N" (questionable data) or line through reading (if measurement is determined to be erroneous) and document reason.

- 7. Other Parameters** – some multi-parameter probes contain sensors for other water quality parameters such as turbidity or suspended solids. If these parameters are also measured, they should be calibrated following manufacturer's specifications prior to use with drift checks performed at the end of each week. Duplicate measurements should be taken at each site and recorded on the stream survey sheet.

## **Protocol D – Habitat Assessment**

### **Biologist/Environmental Specialist**

Habitat assessments are primarily used to determine whether various components of the habitat are factors in fish and aquatic life impairment. A qualitative approach is used to minimize field time while still establishing a standardized assessment procedure that can be used for comparison to ecoregional guidelines. Because of the qualitative nature, the habitat assessment is not considered a cause of impairment without a measured biological response. By close adherence to these assessment guidelines and standardized training, a consistent habitat assessment approach can be achieved.

Although there are four categories on the habitat assessment field sheets, the final state assessment is supporting or non-supporting. Likewise, for each parameter, the final state assessment is comparable to reference or not. Therefore, the primary goal of the habitat assessment is for each biologist to score the assessments so that the same conclusion is reached for total habitat and for each parameter at this scale (either supporting or not supporting).

**Conduct a habitat assessment every time any macroinvertebrate sample is collected. This assessment must be conducted on the same day the biological sample is collected.** Although generally only macroinvertebrate samples are collected, it is important to consider both macroinvertebrates and fish when evaluating habitat. The macroinvertebrate sample is used as an indicator while the habitat assessment is used as a cause of impairment to both fish and aquatic life. It is necessary to walk the entire reach while assessing habitat. It is advisable that two staff members collaborate on the assessment to reduce subjectivity.

Two different habitat assessment field sheets will be used dependent on the Level IV ecoregion and/or stream type at the sampling location (Appendix B). These field sheets are modified from *Rapid Bioassessment Protocols for Use in Wadeable Streams and Rivers* (Barbour et. al., 1999). Habitat guidelines for each ecoregion are provided in Table 3. In ecoregions 65j, 66d, 66e, 66f, 66g, 66i, 66j, 66k, 67f, 67g, 67h, 67i, 68a, 68b, 68c, 68d, 69d, 69e, 71e, 71f, 71g, 71h, and 74a as well as moderate gradient streams in 71i, use the High Gradient Stream (formerly Riffle-Run) assessment field sheet to evaluate habitat. In ecoregions 65a, 65b, 65e, 65i, 73a, 73b and 74b as well as low gradient non-riffle streams in 71i, use the Low Gradient (formerly Glide-Pool) assessment field sheet. Low gradient assessments may also be appropriate in some lower reaches of larger streams in other ecoregions. Copies of these field sheets are located in Appendix B. It is recommended that field sheets be copied to waterproof paper for field use.

Ecoregions designation based on sample point lat and long can be found at <http://tnmap.tn.gov/wpc/>. The Planning and Standards section should be contacted if there is uncertainty about what ecoregion a stream is located in.

Evaluate all ten habitat parameters with 20 being the highest attainable score for each parameter. Scores are divided into four categories (optimal, suboptimal, marginal and poor) with a range of scores possible in each category.

The habitat assessment is based on the entire stream reach (typically 100 meters) with the location of the macroinvertebrate sample the middle of the stream reach. If a longer sampling reach was used to collect macroinvertebrate samples (typically in larger streams or when habitat is scarce) or when collecting fish, the entire sampling reach is used for the habitat assessment. The assessment is an average of the conditions within this reach.

Because this assessment is qualitative, it is essential that assessors follow standardized protocols for scoring especially when assigning categories of Optimal, Sub-optimal, Marginal and Poor. This will enable comparison to ecoregional reference streams that have been assessed following the same standardized procedure.

Two steps are used to assign a habitat score for each parameter. The first step is assigning the parameter a condition category of optimal, suboptimal, marginal, or poor. **Assessors must be careful not to focus on the category names, they are meaningless in the state assessment which is subsequently calibrated to a pass/fail based on the median reference condition for each ecoregion.** The four broad categories are just a convenient tool to quadrisection the various habitat parameters before ranking. These categories are generally based on quantity of the specified parameter. The second step is assigning a numeric score (rank within that category). This is generally based on the quality of the parameter.

**It is important that the assessor does not pre-calibrate the site based on reference expectations while in the field** (For example thinking that streams in a certain area should score optimal because that is as good as it gets, even if they do not meet the description). Scores will be adjusted to ecoregional reference conditions during analysis (Table 2). The best streams in some ecoregions may never fall in the “optimal” category, but will be considered fully supporting based on comparison to reference condition.

The guidelines on the field sheet and in this document should be followed as closely as possible. If the stream does not fit the descriptions, professional judgment should be used with the comment field used to explain scoring. A comment line is available at the bottom of each parameter. Attach additional pages if needed. The station number, assessor and date should be included on any additional pages. Comments can be used to provide additional descriptions, clarify difficult calls, explain atypical stream conditions, specify what characteristic resulted in the score when there are multiple interpretations, describe any factors that should be taken into consideration when interpreting the score or any other information that would help explain the assessment to a reviewer who has not been to the site.

## **Header**

Header information should be filled out completely. It is important to also complete header information on the second page (back) since documents are often sent as pdf files and pages may become separated.

Station ID: Check current stations table in water quality database to see if a station ID has already been assigned to this location. (Do not rely on memory or assume no-one else has ever collected any type of sample at this location. TVA or a permit holder may already have established a station at this location). If a station has not already been assigned, use standard station naming procedure, protocol B. When assigning new stations, make sure the river miles are in line with existing stations (for example river mile 1 should be upstream of river mile 0.5) or notify PAS if existing stations are named inappropriately.

Stream name: Name should match USGS (for example topographic map or GIS coverage), or use unnamed tributary to named receiving stream. Do not use local names that are not on the map.

Station Location: If it is an existing station, use location in current stations table of the water quality database. If it is a new station, use road names or features identifiable on topographic map if possible. Unacceptable location descriptions include:

Upstream STP (specify what STP).

Stinky STP – Specify upstream or downstream and which outfall if there is more than one.

Behind Mr. Jones House. – Mr. Jones may move or next sampler may not know where Mr. Jones lives, use 123 Penny Lane Instead.

Playground (camp site, church, landfill, park etc.) – Use name of playground and road location or other map feature.

Off Highway 123 – Roads are long, add another landmark (for example off Hwy 123 approx. 0.5 mile upstream of intersection with Bumpass Rd.

Highway 123 Bridge – Specify upstream or downstream and how far.

WBID/HUC number: Specify WBID segment (from assessment database) or HUC number if segment number is unknown.

Group: Specify watershed assessment group. This is especially important in watersheds that are split between groups such as 06010102, 06010201 and 06020001.

**Habitat Assessed By:** Include initials of staff member(s) who scored the habitat assessment. Do not include any team members who were not involved with habitat assessment.

**Date:** Enter date of assessment (month/day/year)

**Time:** Enter time (24 hour clock)

**Ecoregion:** Specify ecoregion of stream reach. If questionable, check station location at <http://tnmap.tn.gov/wpc/>.

**Circle if this is a consensus or duplicate assessment, otherwise leave blank.**

**Associated Log #:** Record the log number of the biological sample collected at the same time. (If both macroinvertebrate and periphyton samples were collected, record the macroinvertebrate log number.)

**Fill in Station ID, date and initials of assessor on back of field sheet. (If field sheet is faxed or single-side copied at a later date, this will help identify the second half of the assessment if they are separated).**

**Note: If this is a QC, two separate habitat field sheets should be completed independently. Consensus scores may be marked on one of the field sheets (differentiate between investigator and consensus) or a separate sheet may be used.**

## **Protocol D-1: Moderate to High Gradient Habitat Assessment Field Sheet.**

The moderate to high gradient habitat assessment field sheet (Appendix B) will be suitable for most wadeable streams in middle Tennessee (except for some streams in the Inner Nashville Basin – 71i) and in east Tennessee. It will also be used for two ecoregions in west Tennessee; the Transition Hills (65j) and Bluff Hills (74a).

If riffles are not present due to disturbances such as sedimentation, sludge deposits or channel alterations, but the slope is moderate to high gradient, these field sheets will still be used to evaluate the stream. Some moderate to high gradient streams naturally do not have riffles (steep mountain streams or moderate gradient bedrock streams) however they should still be evaluated with this field sheet. The only time a low gradient field sheet should be used in these ecoregions is if the stream is in a low gradient area (sometimes occurs near the mouth of large streams). Note that the ecoregion reference guidelines cannot be used in low gradient streams in these ecoregions or for non-wadeable streams. Therefore, a suitable upstream or watershed reference must be selected for comparison. In these cases, the test stream should score within 75% of the “reference” stream to have comparable habitat.

### **1. Epifaunal Substrate/Available Cover**

When assessing this parameter, look at various types of natural structures available to macroinvertebrates and/or fish throughout the entire reach. Look for habitat that provides refugia, feeding, spawning or nursery functions. Do not count “newly fallen trees, leaf litter that is not decaying or unstable habitats that will be washed out. Also do not include artificial habitat such as fish attractors, tires, appliances, rip-rap, etc.

Natural habitats that are typically found in moderate to high gradient streams include:

- Cobble riffles
- Gravel riffles
- Bedrock crevices
- Boulders (Fish cover)
- Pool rock
- Run Rock
- Submerged trees (not newfall)
- Snags
- Decaying leaf litter
- Rock overhangs (Fish cover)
- Undercut banks
- Submerged Roots
- Macrophyte beds
- Mossy rocks

To assign a condition category, first look at how much of the stream reach is covered by natural, stable, productive habitat. The numeric score (rank) within the condition category is assigned based on the variety and quality of habitat.

For example, in a very high gradient mountain stream, over 70% of the substrate may be available for colonization putting this in the optimal category. Four or more habitats may be present, but is dominated by boulder cover so it may only score a 16. Variations in habitat that provide niches for different faunal types should be considered as different habitat types. For example, cobble in flowing water and cobble in pools count as two types of habitat.

Habitat that is not of sufficient quantity to support faunal populations, does not show evidence of colonization (such as newly fallen leaves), is not productive (such as seamless bedrock) or is likely to wash out should not be included. Artificial or man-made structures such as rip-rap are also not included since the goal is to evaluate natural habitat.

**Optimal** – Over 70% of the stream reach has natural, stable habitat available for colonization by macroinvertebrates and/or fish. Four or more productive habitats are present. Deadfall, leaf litter, snags etc. are not new-fall but show evidence of decay. If less than four habitats are present drop to Suboptimal.

20 – Cobble riffle is the dominant habitat.

19 – Cobble run is the dominant habitat. Cobble riffles are present.

18 – Cobble run is the dominant habitat. Cobble riffles are not present.

17 – Productive habitat other than cobble riffle or run is dominant. Cobble riffles or runs are available.

16 – Productive habitat other than cobble riffle or run is dominant Cobble riffles and runs are absent.

**Suboptimal** – Natural, stable habitat covers 40 – 70% of stream reach. Three or more productive habitats present. If near 70% and more than three habitats are available go to optimal.

15 – Cobble riffle is the dominant habitat.

14 – Cobble run is the dominant habitat. Cobble riffles are present.

13 – Cobble run is the dominant habitat. Cobble riffles are not present.

12 - Habitat other than cobble riffle or run is dominant. Cobble riffles or runs are available.

11- Habitat other than cobble riffle or run is dominant Cobble riffles and runs are absent.

**Marginal** – Natural stable habitat covers 20 - 40% of stream reach **or** only 1 or 2 productive habitats are available in sufficient quantity to support a population. If coverage nears 40% and three or more productive habitats are present go to suboptimal.

10 - Cobble riffle is the dominant habitat.

9 - Cobble run is the dominant habitat. Cobble riffles are present.

8 - Cobble run is the dominant habitat. Cobble riffles are not present.

7 - Habitat other than cobble riffle or run is dominant. Cobble riffles or runs are available.

6 - Habitat other than cobble riffle or run is dominant Cobble riffles and runs are absent.

**Poor** – Less than 20% stable habitat regardless of number of habitats. Lack of habitat is obvious. Substrate unstable or lacking.

5 – At least two natural, stable, productive habitats are present in limited amount including either cobble riffles or runs.

4 – At least two natural, stable, productive habitats are present in limited amount. Cobble or riffle runs are absent.

3 – Cobble riffle or runs is the only habitat.

2 – Only one natural, stable, productive habitat is available. Cobble riffles or runs are absent.

1 – There are no natural, stable, productive habitats within the reach.

**Comments:** Use comment line to indicate what habitats are noticeably missing, or describe any additional factors which could affect interpretation of the score.

## **2. Embeddedness of riffles**

Estimate the percent that rocks are covered or sunken into the silt, sand, or mud of the stream bottom. Ideally, observations should be done in cobble riffle areas. Ideally, riffles should have multiple layers of cobble loosely lying on each other providing niches for macroinvertebrates and fish between and under the rocks. Gravel riffles or cobble/gravel runs may be substituted if necessary. However, make sure riffles are not absent due to sedimentation (in which case the parameter should score 1).

In moderate to high gradient streams that naturally do not have cobble riffles (i.e. extremely high gradient boulder streams or some moderate gradient bedrock streams) the parameter would score lower due to lack of niche space even if embeddedness is not high.).

Two factors should be evaluated for this parameter.

To determine the condition category, estimate the amount to which the rock is surrounded by fine sediment. Fine sediments are silt, clay, sand, sludge etc. Discoloration on the bottom and sides of rocks is a good way to determine the percent of embeddedness. However, take care that additional cobble layers are not buried in sediment and are not visible.

To select the score within the category, examine the amount of niche space that is provided by layering of cobble (ideal). There should be lots of sediment free spaces between and under rocks for macroinvertebrates and small fish to live. If the stream type is not a cobble-riffle, other examples of riffle or run niches affected by embeddedness include the bottom area of round boulders where it curves into the substrate or the spaces between gravel in a bedrock fissure. In moderate gradient bedrock streams without gravel (for example those with bedrock shelves) examine loose rocks or slabs in areas of relatively fast flow. These are less productive and should be scored lower in the selected condition category.

**Optimal:** Gravel, cobble and boulders are 0 - 25% surrounded by fine sediment. If embeddedness is close to 25% use quality of niche space to differentiate between optimal and suboptimal condition categories. Optimal would be layered cobble. To determine the rank within this category, consider the available niche space.

20 – Niche spaces are free of sediment. Multiple layers of cobble provide niche space for colonization.

19 – Niche spaces are free of sediment but natural substrate does not provide multiple layers or is not cobble.

18 – Small amount of sediment (up to 10%) but niche spaces are not compromised. Multiple layers of cobble are available for colonization.

17 – Small amount of sediment (up to 10%) but niche spaces are not compromised. Natural substrate does not provide multiple layers.

16 – Sediment is more pronounced affecting up to 25% of niche space. Multiple layers of cobble are available for colonization.

**Suboptimal:** Gravel, cobble and boulders are 25% - 50% surrounded by fine sediment. If embeddedness is close to 25% use quality of niche space to differentiate between optimal and suboptimal condition categories. Optimal would be layered cobble. Likewise as number approaches 50% use quality of niche space to differentiate between suboptimal and marginal. Suboptimal would be layered cobble.

15 – Approximately 25% of niche space is affected. Substrate is not layered cobble.

14 – Approximately 30 - 35% of niche space affected. Substrate is layered cobble.

13 – Approximately 40 - 45% of niche space affected. Substrate is layered cobble.

12 – Approximately 30 - 45% of niche space affected. Substrate is not layered cobble

11 – Approximately 50% niche space is affected. Substrate is layered cobble.

**Marginal:** Gravel, cobble and boulders are 50% - 75% surrounded by fine sediment. As amount approaches 50%, use quality of niche space to differentiate between suboptimal and marginal condition categories. Suboptimal would be layered cobble.

10 – Approximately 50% of niche space affected. Substrate is not layered cobble.

9 – Approximately 55 - 65% of niche space affected. Substrate is layered cobble.

8 – Approximately 55 - 65% of niche space affected. Substrate is not layered cobble

7 – Approximately 70 - 75% of niche space affected. Substrate is layered cobble.

6 – Approximately 70 - 75% of niche space is affected. Substrate is not layered cobble.

**Poor:** Gravel, cobble and boulders are more than 75% surrounded by fine sediment.

5 – Approximately 80 - 85% of niche space affected. Substrate is layered cobble.

4 – Approximately 80 - 85% of niche space affected. Substrate is not layered cobble.

3 – Approximately 90 - 95% of niche space affected. Substrate is layered cobble

2 – Approximately 90 - 95% of niche space affected. Substrate is not layered cobble.

1 – Niche space is completely filled in by sediment.

**Comments:** Use comment line to describe type of sediment (sand, silt, clay, sludge etc.) and to describe any additional factors that would affect scoring.

### 3. Velocity/Depth Regime

Determine the patterns of velocity and depth. The four basic patterns are slow-deep, slow-shallow, fast-deep, and fast-shallow. The most productive streams will have all four patterns present. Differentiation between regimes will vary depending on stream size. Focus on habitat function. For example does the difference between fast-deep and fast-shallow in a small stream provide habitat for different taxa.

Condition Category is based on how many of the four regimes are present. Ranking is based on which ones are prevalent.

**Optimal:** All four velocity/depth regimes are present.

20 – All four velocity/depth regimes are equally available.

19 – Fast-shallow is the dominant regime.

18 – Slow-shallow is the dominant regime.

17 – Fast-deep is the dominant regime.

16 – Slow-deep is the dominant regime.

**Suboptimal:** Only 3 of the 4 velocity/depth regimes are present.

15 - Slow-deep is the only missing regime

14 - Fast-shallow is dominant

13 - Slow-shallow is dominant

12 - Fast-deep is dominant

11 – Slow deep is dominant.

**Marginal:** Only 2 of the 4 regimes are present. Both regimes are adequate to support aquatic population adapted to that habitat.

10 - Fast-Shallow and Slow-Shallow are present

9 - Fast-Shallow and Fast-Deep are present

8 - Fast-Shallow and Slow-Deep are present

7 - Slow-Shallow and Fast-Deep are present

6 - Fast-Deep and Slow-Deep are present.

**Poor:** One of the 4 regimes dominates the reach (if another is present it is too small or infrequent to sustain an aquatic population adapted to that habitat.

5 - Fast-Shallow is dominant a second regime may be present but is too infrequent to sustain a population.

4 - Slow-Shallow is dominant a second regime may be present but is too infrequent to sustain a population.

3 - Fast-Deep is dominant a second regime may be present but is too infrequent to sustain a population.

2 - Slow-Deep is dominant a second regime is present but is too infrequent to sustain a population.

1 - Slow-Deep is the only regime present.

**Comments:** Use the comment field to describe any additional factors that may affect scoring.

#### **4. Sediment Deposition**

This parameter is designed to measure the changes that have occurred to the stream bottom and flow patterns as a result of the deposition of small particles (gravel, sand, silt). It differs from embeddedness which is designed to measure loss of niche space.

Select condition category by estimating the percent of the stream bottom that is affected by sediment deposition. Areas of deposition occur in pools, bends, natural or man-made constrictions and other areas of slower flow. Deposition is also observable through the formation of islands, point bars (areas of increased deposition at the beginning of a meander that increase in size as the channel is diverted toward the outer bank) or shoals. Only areas of new, un-vegetated deposition on bars and islands should be considered when scoring.

Rank within each category is determined by the areas most affected by sediment deposition. Sediment in pools or slow areas will score higher than sediment on point bars and islands.

**Optimal:** Sediment deposition affects less than 5% of stream bottom in quiet areas. New deposition on islands and point bars is absent or minimal.

20 – No islands or point bars. No sediment in pools or slow areas.

19 – No new deposition on stable islands or point bars. No sediment in pools or slow areas.

18 - No new deposition on islands or point bars. Small amount of sediment in pools or slow areas.

17 – Slight amount of new deposition on islands or point bars. No sediment in pools or slow areas.

16 – Slight amount of new deposition on islands or point bars. Small amount of sediment in pools or slow areas. Almost 5% of bottom area affected.

**Suboptimal:** Sediment deposition affects 5 – 30% of stream bottom. Slight deposition in pool or slow areas. Some new deposition on islands and point bars.

15 – Sediment deposition affects 5 – 15% of the bottom substrate. Most of the deposition is in pools or bends with little new accumulation on islands or point bars.

14 – Sediment deposition affects 5 - 15% of the bottom substrate. Deposition occurs in both pool areas and as new accumulation on bars and islands.

13 – Sediment deposition affects 20 – 25% of the bottom substrate. Most of the deposition is in pools or bends with little new accumulation on islands or point bars.

12 – Sediment deposition affects 20 – 25% of the bottom substrate. Deposition occurs in both pool areas and as new accumulation on bars and islands.

11 – Sediment deposition affects 30% of the bottom substrate. The majority of deposition is in pools or bends with little new build-up of islands or point bars. Move to marginal if build-up of islands and point bars approaches 30%.

**Marginal:** Sediment deposition affects 30 – 50% of stream bottom. Sediment deposits at obstructions, constrictions and bends. Moderate deposition of pools.

10 – Sediment deposition affects 30% of stream bottom. Sediment deposits on bars and islands as well as pools and bends.

9 – Sediment deposition affects 35 – 45% of stream bottom. Most of deposition is in pools rather than build-up of bars and islands.

8 – Sediment deposition affects 35 – 45% of stream bottom. Moderate deposition of pools as well as new deposition on bars and islands.

7 – Sediment deposition affects almost half of the stream bottom. Most of deposition is in pools rather than new deposition on bars and islands.

6 – Sediment deposition affects almost half of the stream bottom. New sediment accumulation on bars and islands as well as in pools.

**Poor:** Heavy deposits of fine material. Increased bar development. More than 50% of the stream bottom changing frequently. Pools almost absent due to substantial sediment deposition.

5 – Approximately 50% of the bottom substrate is affected by sediment deposition.

4 – Approximately 60% of the bottom substrate is affected by sediment deposition.

3 - Approximately 70% of the bottom substrate is affected by sediment deposition.

2 – Approximately 80% of the bottom substrate is affected by sediment deposition.

1 – Sediment blankets stream bottom pools absent due to sediment deposition.

**Comment:** Use comment field if needed to describe other factors related to score.

## 5. Channel Flow Status

Condition category will be selected based on the amount of the streambed covered by water. Rank within the category will be determined by how much productive habitat is exposed. **If water has been backed up by obstructions (such as beaver dam, log jams, debris plugs) move assessment reach above or below the affected area.** If this is not possible, determine whether sampling is appropriate or should be postponed until conditions are more representative of actual stream conditions. Use comment field to explain if necessary. Assess flow status based on what is submerged during normal flow conditions, for example naturally exposed gravel beds do not indicate exposed habitat. Use comment field to note if flow is reduced due to natural low flow conditions, drought, irrigation, municipal water withdrawal, impoundment etc.

**Optimal:** Water reaches base of both lower banks and streambed is covered by water throughout the reach. Minimal amount of productive habitat is exposed. Riffle areas are fully submerged.

20 – Water is above the base of each bank. No productive habitats are exposed.

19 – Productive habitats including tree roots and riffles are submerged but some undercut areas may be above water. Riffle areas are fully submerged.

18 –Some tree roots are exposed but there is plenty of submerged root habitat available. Riffle areas are fully submerged. (If rooted bank habitat is naturally not present, score 16)

17 – If rooted bank habitat is present, some tree roots are exposed but there is plenty of submerged root habitat available. Small areas of riffles may be minimally affected due to shallow water depth but riffle habitat is not compromised.

16 – Water reaches base of both banks and water still covers streambed. Root, riffle or other habitat is compromised due to water depth although is still available for colonization.

**Suboptimal:** Water covers more than 75% of the streambed but is less than 100% or 25% of productive habitat is exposed.

15 – One or more habitats may be absent due to water depth but riffle areas are not affected. (If productive riffle habitat is naturally not present score 11).

14 – Water depth in riffles is reduced but this has not affected size or frequency of riffles.

13 – Some riffle areas have become limited in size but none are totally exposed.

12 – A few smaller riffles have become exposed.

11 - Up to 25% of small riffles have become exposed or productive riffle habitat is not naturally available.

**Marginal:** Water covers 25% - 75% of the streambed, **and/or** stable habitat is mostly exposed.

10 – Water covers 75% of channel. Most small riffles are exposed. (If productive riffle habitat is naturally not present score 11).

9 – Water covers 60 – 70% of streambed. All smaller riffles are exposed. Large riffles do not have significant exposed areas.

8 – Water covers about 50% of the streambed. Larger riffles are still present but are reduced in size.

7 – Water covers 30 – 40% of the streambed. Majority of riffle areas are exposed although small areas of largest riffles are still submerged.

6 – Water covers about 25% of streambed. Riffle areas are exposed although other rock habitat is available in run areas.

**Poor:** Very little water in channel and mostly present as standing pools. Little or no productive habitat due to lack of water.

- 5 – All riffles exposed. Runs extremely reduced. Very limited rock habitat available in running water.
- 4 – All riffles exposed. Runs reduced to trickles. No rock habitat available in running water.
- 3 – All riffles and runs exposed. Long stretches of pooled water provide some productive habitat. Stream may be flowing below surface between pools.
- 2 – Stream reduced to isolated pools with no productive habitat.
- 1 – Stream is dry

**Comment:** Use comment field to explain factors affecting the amount of water in the stream including natural (beaver activity, karst, drought etc.) and unnatural (dams, log jams at bridges, water withdrawal etc).

## **6. Channel Alteration**

Determine how much, if at all, the stream reach has been altered by man-made activities (not beavers). Channel alteration is present when artificial embankments, riprap, and other forms of artificial bank stabilization or structures are present; when the stream is very straight for significant distances; when dams, culverts or bridges are present; when dredging or gravel/rock removal is evident, when snags/deadfall is removed, off-road vehicle activity has altered the bottom contours/compressed riffles and when other such artificial changes have occurred. Bridges, dams or other man-made structures upstream or downstream of the assessed reach should be considered if they affect flow patterns in the targeted reach.

**Optimal:** Channelization, gravel dredging, rock removal and off-road vehicle activity (past or present) absent or minimal. Stream has natural meander pattern. Shoring structures including riprap are absent. Artificial structures are not present in stream reach. Bridges, culverts, dams or other structures upstream or downstream are not affecting the stream reach.

- 20 – Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. There is no evidence of past or present gravel dredging or rock removal. There is no evidence of off-road vehicle activity. Stream has normal meander pattern.
- 19 - Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. Evidence of past rock removal is minimal. There is no evidence of gravel/sand dredging or 4-wheel activity. Stream flow pattern and habitat not affected.

18 – Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. Evidence of past gravel/sand dredging is minimal. There is no evidence of 4-wheel activity. Stream flow pattern and habitat not affected.

17 – Past channel alteration in small area (less than 5% of reach). Stream flow pattern not affected. Modification is stable, well vegetated with natural vegetation, no erosion potential. There are no artificial structures in stream reach or within impact area. There is no evidence of 4-wheel activity.

16 – Evidence of past 4-wheel vehicle activity. Riffle and run areas intact, stream contours not affected. Artificial structures may be present outside of the reach but are not affecting the flow patterns, habitat or stream contours within reach.

**Suboptimal:** Evidence of channelization, dredging or 4-wheel activity up to 40%. May be longer reach if channelization is historic). Channel has stabilized and altered flow pattern does not affect colonization. Bridges, culverts, shoring or other artificial structures either within or outside of reach have not affected natural flow patterns.

15 – Historic channelization has stabilized (May also include pre-civil war rock walls.)  
Modification is stable, well vegetated with natural vegetation and no erosion potential.

14 – Bridge, culverts, shoring or artificial structures may be present but do not affect natural flow patterns in reach. (Includes structures upstream or downstream as well as within reach).

13 – Recent off-road vehicle activity in stream. Riffle or run areas slightly disturbed. Natural stabilization and re-colonization expected.

12 – Evidence of recent rock removal or gravel/sand dredging has had slight impact on reach. Natural stabilization and re-colonization is expected.

11- New channelization in up to 40% of stream reach. Modification is stable, well vegetated with natural vegetation, no erosion potential. (If not stable score 10).

**Marginal:** Channelization, dredging or 4-wheel activity 40 to 80% or less amount of channelization that has not stabilized. Bridges, culverts, shoring or other artificial structures either within or outside of reach may have slightly affected natural flow patterns.

10 – Less than 40% of reach altered but has not stabilized.

9 – 40 - 80% of reach has been channelized but is stable with natural vegetation.

8 – Bridge, culverts, shoring or artificial structures have slight affect on natural flow patterns in reach. (Includes structures upstream or downstream as well as within reach).

7 – Dredging, rock removal, 4-wheeling or other in-stream activity has impacted habitat in 40 - 80% of reach.

6 – 40 - 80% of reach has been altered and has not stabilized.

**Poor:** Over 80% of the stream reach channelized, dredged or affected by off-road vehicles, instream habitat greatly altered or removed entirely or artificial structures within reach or upstream/downstream of reach have greatly affected natural flow patterns.

5 – Over 80% of the stream reach has been channelized but is stable with natural vegetation.

4 – Over 80% of the stream reach is channelized and has been stabilized with artificial shoring.

3 – Over 80% of the stream reach is channelized and has not stabilized.

2 – Impoundment, bridge or other artificial structure has a high level of impact on normal stream flow and/or channel pattern. Include upstream or downstream structures that have seriously affected the sample reach.

1 – At least part of stream reach is in concrete or other artificial channel (including culverts).

**Comment:** Use comment field to indicate type of channel alteration (channelization, man-made dams, 4-wheel activity, construction vehicles). Also make note if beaver activity has altered stream (this is a natural condition so would score 20 if there are no artificial modifications but needs to be noted).

## **7. Frequency of Riffles, Bends or Other Re-Oxygenation Zones**

Determine the pattern of stream morphology by estimating the sequencing of riffles. This is the only parameter where the hydrologic (not biological) definition of riffle will apply. Any swift moving re-oxygenation zones count, including bedrock riffles, large boulders, and bends. These areas provide diversity of habitat, control flow and provide refugia during storm events as well as re-oxygenate the water. To score this parameter, a longer segment may need to be incorporated into the evaluation if there are not at least 3 re-oxygenation areas within the sample reach. It may be necessary to pace off or measure distances. In larger streams where bends are the only re-oxygenation areas, maps may be used to determine frequency. Frequency will determine the condition category. Quality of habitat provided will determine the rank within the category.

**Optimal:** Occurrence of re-oxygenation zones relatively frequent. Distance between areas divided by average width of the stream <7:1.

20 – Re-oxygenation areas are high quality cobble riffles.

19 – Re-oxygenation areas are high quality gravel riffles.

18 – Re-oxygenation areas are not high quality cobble/gravel riffle but provide productive habitat (may include cobble runs or lower quality cobble riffles).

17 – Re-oxygenation areas are primarily bedrock, large boulder or other relatively unproductive habitat.

16 – Re-oxygenation areas are bends.

**Suboptimal:** Occurrence of re-oxygenation zones infrequent; distance between areas divided by average width of the stream is from 7 to 15.

15 – Re-oxygenation areas are high quality cobble riffles.

14 – Re-oxygenation areas are high quality gravel riffles.

13 – Re-oxygenation areas are not high quality cobble/gravel riffle but provide productive habitat (may include cobble runs or lower quality cobble riffles).

12 – Re-oxygenation areas are primarily bedrock, large boulder or other relatively unproductive habitat.

11 – Re-oxygenation areas are bends.

**Marginal:** Occasional re-oxygenation area. Distance between areas divided by average width of the stream is over 15 and up to 25.

10 – Re-oxygenation areas are high quality cobble riffles.

9 – Re-oxygenation areas are high quality gravel riffles.

8 – Re-oxygenation areas are not high quality cobble/gravel riffle but provide productive habitat (may include cobble runs or lower quality cobble riffles).

7 – Re-oxygenation areas are primarily bedrock, large boulder or other relatively unproductive habitat.

6 – Re-oxygenation areas are bends.

**Poor:** Generally all flat water or flat bedrock. Little opportunity for re-oxygenation. Distance between areas divided by average width of the stream is over 25.

5 – Re-oxygenation areas are high quality cobble riffles.

4 – Re-oxygenation areas are gravel riffles.

3 – Re-oxygenation areas are not high quality cobble/gravel riffle but provide productive habitat (may include cobble runs or lower quality cobble riffles).

2– Re-oxygenation areas are primarily bedrock, large boulder or other relatively unproductive habitat.

1 – Re-oxygenation areas are bends.

**Comments:** Use comment field to describe other factors affecting the score if needed such as atypical reoxygenation areas or poor quality riffles.

## 8. Bank Stability

Determine whether the stream banks are eroded or have the potential for erosion. Steep banks are more likely to collapse and suffer from erosion than are gently sloping banks, and are therefore considered less stable. Signs of erosion include crumbling, unvegetated banks, sloughing, exposed tree roots, and exposed soil. Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

**Optimal:** Banks stable, evidence of erosion or bank failure absent or minimal; little potential for future problems, < 5% of the bank affected.

10 – No signs of instability evident. Banks sloping. Little erosion potential.

9 – Some erosion evident or steep banks or some potential for erosion.

**Suboptimal:** Moderately stable, infrequent, small areas of erosion. 5 – 30% of bank in reach has areas of erosion.

8 – 5 - 15% of bank has areas of healed over erosion.

7 – 5 - 15% of bank has areas of erosion or other signs of instability. Some are not healed over.

6 – 20 - 30% of bank has areas of erosion or other signs of instability. If approaching 30%, score lower if banks are steep.

**Marginal:** Moderately unstable; 30 - 60% of bank in reach has areas of erosion or other signs of instability; high erosion potential during floods.

5 – 30 - 40% of bank has areas of erosion or other signs of instability. If approaching 40%, score lower if banks are steep.

4 – 40 - 50% of bank has areas of erosion or other signs of instability. If approaching 50%, score lower if banks are steep.

3 - 50 - 60% of bank has areas of erosion or other signs of instability. If approaching 60%, score lower if banks are steep or sloughing.

**Poor:** Unstable: many eroded areas; raw areas frequent along straight sections and bends; obvious bank sloughing; Over 60% of banks has areas of erosion or other signs of instability.

2 – 60 - 75% of bank has areas of erosion or other signs of instability.

1 – 80 - 90% of bank has areas of erosion or other signs of instability.

0 – There are no stable areas on bank.

**Comment:** Use comment field if needed to describe additional factors affecting scoring.

## 9. Bank Vegetative Protection

Determine the type and quality of vegetation on the stream bank. This is the area from the base of the bank to the top of the bank. The object is to determine the ability of the bank to resist erosion as well as the ability of the plants to uptake nutrients, control instream scouring, supply food to shredders and provide stream shading. Streams that have various classes of native vegetation providing full natural plant growth including groundcover, shrubs, understory trees and large trees will score highest.

In some regions, the introduction of exotics, such as kudzu, privet or honeysuckle, has virtually replaced all native vegetation. Although exotics may provide erosion control, they do not provide ideal food and habitat to stream organisms that have evolved to utilize native species. Banks that are dominated by non-native vegetation should score lower. A list of commonly encountered non-native species can be found in Appendix B. Species information, county distribution and pictures can be found at [http://www.tneppc.org/Invasive\\_Exotic\\_Plant\\_List/The\\_List-by\\_habit.htm](http://www.tneppc.org/Invasive_Exotic_Plant_List/The_List-by_habit.htm)

Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

Condition category is determined by estimating the amount of bank covered by undisturbed native vegetation. Rank is determined by complexity of vegetation type.

Condition category is determined by estimating the amount of bank covered by undisturbed native vegetation. Rank is determined by complexity of vegetation type.

**Optimal:** More than 90% of the streambank surfaces and immediate riparian zone covered by undisturbed vegetation. All four classes (mature trees, understory trees, shrubs, groundcover) are represented. All plants allowed to grow naturally. All plants are native.

10 - No disruption. All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are represented and allowed to grow naturally.

9 - Minimal disruption affecting less than 10% of stream bank. All classes of vegetation are represented and allowed to grow naturally.

**Suboptimal:** The majority (70 - 90%) of the bank is covered by undisturbed native vegetation. One class may not be not well represented. Disruption evident but not affecting full plant growth. Non-native vegetation may be present but rare (< 30%).

8 – Over 90% of bank area covered by native vegetation but one class not well represented.

7 – 70 - 90% of bank area covered by native vegetation. All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are well represented and allowed to grow to full height.

6 – 70 - 90% of bank area covered by vegetation but one class not well represented. Other classes allowed to grow to full height. Non-natives may be present but do not affect natural vegetation growth

**Marginal:** 50 - 70% of the bank covered by undisturbed vegetation. Non-native vegetation may be common (30 - 50%). Two classes of vegetation may not be well represented.

5 – All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are represented. If approaching 70% score suboptimal 7 if all vegetation allowed to grow to full height.

4 – One class of vegetation not well represented or not allowed to grow to full height. If approaching 70% score suboptimal 6 if all vegetation is native and allowed to grow to full height.

3 – Two classes of vegetation not well represented or not allowed to grow to full height or non-native vegetation is common.

**Poor:** Less than 50% of the bank is covered by undisturbed vegetation or more than two classes of vegetation are not well represented or most vegetation has been cropped. Non-native vegetation may be dominant (> 50%).

2 – Vegetation that is present is mostly native and allowed to grow to full height.

1 – Most vegetation is cropped and not allowed to grow to full height or non-native vegetation is dominant.

0 – Bank vegetation is absent or too sparse to provide bank protection or habitat.

**Comment:** Use the comment field to describe what class of plants are missing and/or describe non-native plants.

## 10. Riparian Vegetative Zone Width

Estimate the width of natural vegetation from the top of the stream bank out through the riparian zone (approximately 18 meters). Disturbance to the riparian zone occurs when there are roads, parking lots, fields, row crops, lawns, parks, picnic areas, bare soil, buildings, logging, campgrounds, golf courses, power-lines or other human activity.

Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

Condition category is determined by estimating the average width of the riparian zone from the top of the stream bank, outward. Generally the riparian ends at first indication of human disturbance with the exception of un-paved footpaths or trails in an otherwise undisturbed riparian.

Scoring within the category should be based on the level of impact the disturbance has. For example un-grazed fields would score higher than actively grazed fields. Lawns would score higher than paved areas.

Paths, and walkways in an otherwise undisturbed riparian zone may be judged to be minimal disturbance if they are unpaved, narrow and show no evidence of erosion. They should not affect condition category, but should lower score one point within category.

**Optimal:** Average width of riparian > 18 meters throughout reach.

10 – There is no human disturbance.

9 – Human disturbance minimal, for example, an un-paved footpath.

**Sub-optimal:** Average width of riparian 12 – 18 meters throughout reach.

8 – Human disturbance, after 12 meters of undisturbed riparian is minimal, for example an un-grazed hay field or areas of riparian that are less than 18 meters are small.

7 – Human disturbance, after 12 meters is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.

6 – Human disturbance, after 12 meters is not vegetated, for example paved or gravel lots, roads, bare dirt.

**Marginal:** Average width of riparian 6 – 11 meters throughout reach.

5 – Human disturbance, after 6 meters of undisturbed riparian is minimal, for example an un-grazed field, or areas that are less than 12 meters are small.

4 – Human disturbance, after 6 meters is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.

3 – Human disturbance, after 6 meters is not vegetated, for example paved or gravel lots, roads, bare dirt.

**Poor:** Average width of riparian < 6 meters throughout reach.

2 – Human disturbance is minimal, for example an un-grazed field or areas that are less than 6 meters are small.

1 – Human disturbance is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.

0 – Human disturbance has removed all vegetation, for example paved or gravel lots, roads, bare dirt.

**Comment field:** Indicate type of disturbance and any additional factors affecting score.

## **Protocol D-2: Low Gradient Habitat Assessment Field Sheet.**

The low gradient habitat field sheet (Appendix B) is used for low gradient streams. This will include streams in ecoregions 65abei, 73ab and 74b in west Tennessee as well as some streams in ecoregion 71i in middle Tennessee. This assessment may also be appropriate in lower reaches of larger streams in other ecoregions.

### **1. Epifaunal Substrate/Available Cover**

When assessing this parameter, look at various types of natural structures available to macroinvertebrates and/or fish throughout the entire reach. Look for habitat that provides refugia, feeding, spawning or nursery functions. Do not count newly fallen trees, leaf litter that is not decaying or unstable habitats that will be washed out. Also do not include artificial habitat such as fish attractors, tires, appliances, rip-rap etc.

Habitats that are generally found in low gradient streams include:

- Undercut banks
- Submerged roots
- Macrophyte beds
- Submerged trees (not newfall)
- Snags
- Decaying leaf litter
- Run rocks
- Pool Rocks
- Gravel riffles
- Sediment
- Bedrock fissures

To assign a condition category, first look at how much of the stream reach is covered by natural, stable, productive habitat. The numeric score (rank) within the condition category is assigned based on the variety and quality of the habitat. Variations in habitat that provide niches for different faunal types should be considered as different habitat types. For example, undercut banks with submerged tree roots should be considered separate from undercut banks with fine grassy roots.

Habitat that is not of sufficient quantity to provide faunal populations, does not show evidence of colonization (such as newly fallen leaves), is not productive (such as shifting sand) or is likely to wash out should not be included. Artificial structures such as rip-rap are also not included since the goal is to evaluate natural habitat.

**Optimal** – Over 50% of the stream reach has natural, stable habitat available for colonization by macroinvertebrates and/or fish. Three or more productive habitats are present. Deadfall, leaf litter, snags etc. are not new-fall but show evidence of decay. If less than three habitats are present drop to suboptimal.

20 – Deadfall and snags are the dominant habitat. At least two other habitats are available.

19 – Rooted banks are the dominant habitat. At least two other habitats are available.

18 – Macrophyte beds are the dominant habitat. At least two other habitats are available.

17 – Leaf litter is the dominant habitat. At least two other habitats are available.

16 – Another habitat is dominant. At least two other habitats are available.

**Suboptimal** – Natural stable habitat covers 30 - 50% of stream reach or less than three habitats are present. If nearing 30% and only one habitat is present, drop to marginal.

15 – Deadfall and snags are the dominant habitat

14 – Rooted banks are the dominant habitat

13 – Macrophytes beds are the dominant habitat.

12 – Leaf litter is the dominant habitat

11 – Another habitat is dominant.

**Marginal** – Natural stable habitat covers 10 – 30% of the stream reach. Availability less than desirable, substrate frequently disturbed or removed. Habitat diversity is reduced. If nearing 10% and only one habitat is available, drop to poor.

10 – Deadfall and snags are the dominant habitat.

9 – Rooted banks are the dominant habitat

8 – Macrophyte beds are the dominant habitat

7 – Leaf litter is the dominant habitat

6 – Another habitat is dominant.

**Poor** – Less than 10% stable habitat. Lack of habitat is obvious; substrate unstable or lacking.

5 – Rooted banks are the dominant habitat.

4 – Deadfall and snags are the dominant habitat

3 – Macrophyte beds are the dominant habitat

2 – Leaf litter or another habitat is dominant.

1 – Habitat is lacking.

**Comments:** Use comment line to indicate what habitats are noticeably missing, or describe any additional factors which could affect interpretation of the score.

## **2. Channel Substrate Characterization** (replaces Pool Substrate Characterization)

Evaluate the type and condition of the bottom substrate in the channel. Firmer sediment such as gravel, firm sand, and rooted aquatic plants support a wider variety of organisms and should be scored higher than a substrate dominated by soft sand, mud or bedrock with no plants. In addition, a stream that has a uniform substrate will support fewer types of organisms and should score lower than a stream that has a variety of substrate type. Root mats for this parameter are those within the bottom substrate of the channel and should not be confused with rooted undercut banks. Firm sand is desirable while soft sand will score lower. Fissured bedrock with crevices and rock shelves will score higher than smooth bedrock.

The type of substrate will determine the condition category. Rank within the category will be based on the ratio of substrate type.

**Optimal** – Good mixture of substrate materials with gravel and firm sand prevalent. Root mats and submerged vegetation are common.

20 – Even mix of gravel and firm sand. Both root mats and submerged vegetation are common.

19 – Mixture of substrate including firm sand. Gravel is dominant. Both root mats and submerged vegetation are common.

18 – Mixture of substrate including firm sand. Gravel is dominant. Either root mats or submerged vegetation is missing.

17 – Mixture of substrate including gravel. Firm sand is dominant. Both root mats and submerged vegetation are common.

16 – Mixture of substrate including gravel. Firm sand is dominant. Either root mats or submerged vegetation is missing.

**Suboptimal** - Mixture of soft sand, mud or clay. Substrate may also be fissured bedrock. Some root mats and submerged vegetation present.

15 – Mixture of soft sand, mud and clay. No substrate dominant. Both root mats and submerged vegetation present.

14 – Mixture of soft sand, mud and clay, mud dominant. Both root mats and submerged vegetation present.

13 – Mixture of soft sand and mud, mud dominant. Either root mats or submerged vegetation is missing.

12 – Mixture of soft sand and clay or substrate is fissured bedrock with frequent fissures and shelves. Some root mats and submerged vegetation present.

11 – Mixture of soft sand and clay or substrate is fissured bedrock with frequent fissures and shelves. Either root mats or submerged vegetation is missing.

**Marginal** – All mud, clay or soft sand bottom; substrate may also be fissured bedrock; little or no root mat; no submerged vegetation present.

10 – Mud bottom, some root mat present.

9 – Soft Sand bottom, some root mat present.

8 – Clay bottom, some root mat present.

7 – Mud or fissured bedrock bottom, no root mat present.

6 – Soft sand or clay bottom, no root mat present.

**Poor** – Hard-pan clay, conglomerate or flat bedrock; no root mat or vegetation.

5 – Predominantly flat bedrock, other non-bedrock substrate available.

4 – Predominantly flat bedrock, infrequent crevices and/or shelves provide some habitat.

3 – Predominantly conglomerate substrate.

2 – Predominantly flat bedrock substrate.

1 – Predominantly hard-pan clay substrate.

**Comments:** Use comment field if needed to clarify scoring or describe substrate.

### **3. Pool Variability**

Rate the overall mixture of pool types found in the stream, according to size and depth (this will vary depending on the size of the stream). The four basic types of pools are large-shallow, large-deep, small-shallow, and small-deep. A stream having many different pool types will support a wider variety of aquatic species and should score higher. The variety of pool types will determine condition category. The quality of these pools will determine rank within the category.

**Optimal:** Even mix of large-shallow, large-deep, small-shallow, small-deep pools present.

20 – Some pools are at least 1 meter deep and are of sufficient length to support fish populations.

19 – Large-deep pools are less than 1 meter but are of sufficient size and depth to support fish populations.

18 – Large-deep pools are at least 1 meter providing distinct habitat but are of insufficient length to support fish populations.

17 – Smaller stream, deep pools provide distinct benthic habitat from shallow pools but are not of sufficient depth to support fish populations.

16 – Although all 4 pool types are available, some may not provide distinct faunal habitat due to small stream size.

**Sub-optimal:** Majority of pools large-deep; very few shallow.

15 – Some pools are at least 1 meter deep and are of sufficient length to support fish populations.

14 – Large-deep pools are less than 1 meter but are of sufficient size and depth to support fish populations.

13 – Large-deep pools are at least 1 meter providing distinct benthic habitat but are of insufficient length to support fish populations.

12 – Smaller stream, deep pools provide distinct benthic habitat but are not of sufficient depth to support fish populations.

11 – Smaller stream, deep pools though present may not provide distinct habitat.

**Marginal:** Shallow pools much more prevalent than deep pools.

10 – Some pools are at least 1 meter deep and are of sufficient length to support fish populations.

9 – Large-deep pools are less than 1 meter but are of sufficient size and depth to support fish populations.

8 – Large-deep pools are at least 1 meter providing distinct habitat but are of insufficient length to support fish populations.

7 – Smaller stream, deep pools are less than 1 meter and are of insufficient size to support fish populations but do provide distinct benthic habitat from shallow pools.

6 – Smaller stream, deep pools though present may not be frequent enough or of sufficient size to provide distinct benthic habitat from shallow pools.

**Poor:** Majority of pools small-shallow or pools absent

5 – Both large-shallow and small-shallow pools present.

4 – Only small-shallow pools present.

3 – Pools absent, although slow current areas are present.

2 – Pools absent, although there are depth changes within channel.

1 – Channel is a continuous run with little or no changes in velocity or depth.

**Comments:** Use the comment field if needed for clarification or to describe atypical characteristics affecting scoring.

#### **4. Sediment deposition**

This parameter is designed to measure the changes that have occurred to the stream bottom and flow patterns as a result of the deposition of small particles (gravel, sand, silt).

Select condition category by estimating the percent of the stream bottom that is affected by sediment deposition. Areas of deposition occur in pools, bends, natural or man-made constrictions and other areas of slower flow. Deposition is also observable through the formation of islands, point bars (areas of increased deposition at the beginning of a meander that

increase in size as the channel is diverted toward the outer bank) or shoals. Only areas of new, un-vegetated deposition on bars and islands should be considered when scoring.

Rank within each category is determined by the areas most affected by sediment deposition. Sediment in pools or slow areas will score higher than sediment on point bars and islands.

**Optimal:** Sediment deposition affects less than 20% of stream bottom in quiet areas. New deposition on islands and point bars is absent or minimal.

20 – No islands or point bars. No sediment in pools or slow areas.

19 – No new deposition on stable islands or point bars. No sediment in pools or slow areas.

18 – No new deposition on islands or point bars. Small amount of sediment in pools or slow areas.

17 – Small amount of new deposition on islands or point bars. No sediment in pools or slow areas.

16 – Small amount of new deposition on islands or point bars. Small amount of sediment in pools or slow areas. Up to 20% of bottom area affected. (As deposition approaches 20% if most of deposition is an increase in island or bars drop to suboptimal.)

**Suboptimal:** Some new increase in bar formation, mostly from gravel, sand or fine sediment (20 - 50%) of the bottom affected. Slight deposition in pools.

15 – Sediment deposition affects 20 - 30% of the bottom substrate. Most of the deposition is in pools or bends with little new accumulation on islands or point bars.

14 – Sediment deposition affects 20 - 30% of the bottom substrate. Deposition occurs in both pool areas and as new accumulation on bars and islands.

13 – Sediment deposition affects 35 - 45% of the bottom substrate. Most of the deposition is in pools or bends with little new accumulation on islands or point bars.

12 – Sediment deposition affects 35 - 45% of the bottom substrate. Deposition occurs in both pool areas and as new accumulation on bars and islands.

11 – Sediment deposition affects 50% of the bottom substrate. Deposition occurs primarily on pool areas. As new accumulation on bars and islands approaches 50% drop to marginal.

**Marginal:** Moderate deposition of new gravel, sand or fine sediment on old and new bars 50-80% of the bottom affected; sediment deposits at obstructions, constrictions, and bends; moderate deposition of pools prevalent.

10 – Sediment deposition affects 50% of stream bottom. Sediment deposits on bars and islands as well as pools and bends.

9 – Sediment deposition affects 55 – 65% of stream bottom. Most of deposition is in pools rather than build-up of bars and islands.

8 – Sediment deposition affects 55 – 65% of stream bottom. Moderate deposition of pools as well as new deposition on bars and islands.

7 – Sediment deposition affects 70 - 80% of the stream bottom. Most of deposition is in pools rather than new deposition on bars and islands.

6 – Sediment deposition affects 70 - 80% of the stream bottom. New sediment accumulation on bars and islands as well as in pools.

**Poor:** Heavy deposits of fine material, increased bar development; more than 80% of the bottom changing frequently; pools almost absent due to substantial sediment deposition.

5 – Approximately 85 - 90% of the bottom substrate is affected by sediment deposition. Pools heavily affected but still present or pools naturally absent.

4 – Approximately 85- 90% of the bottom substrate is affected by sediment deposition. Pools absent due to sediment deposition.

3 - Approximately 95% of the bottom substrate is affected by sediment deposition. Pools heavily affected but still present or pools naturally absent.

2 – Approximately 95% of the bottom substrate is affected by sediment deposition. Pools absent due to sediment deposition.

1 – Sediment blankets 100% of stream bottom.

**Comment:** Use comment field if needed to describe other factors related to score.

## 5. Channel Flow Status

Estimate the degree to which the channel is filled with water. Condition category will be selected based on amount of streambed covered. Rank within the category will be determined by how much productive habitat is exposed. If the stream has no habitat, score lowest rank within condition category and explain in comments. If water has been backed up by obstructions (such as beaver dam, log jams, bedrock during low flow) move assessment reach above or below the affected area or consider postponing sampling until an accurate assessment of stream conditions can be achieved. Assess flow status based on what is submerged during normal flow conditions, for example naturally exposed gravel beds do not indicate exposed habitat. Use comment field to note if flow is reduced due to natural low flow conditions, drought, irrigation, municipal water withdrawal, impoundment etc.

**Optimal:** Water reaches base of both lower banks throughout reach and covers stream bed. Minimal productive habitat is exposed.

20 – Water is above the base of each bank and no productive habitats are exposed.

19 – Roots are submerged but some undercut areas may be above water. Other productive habitats are not affected.

18 – Some shallow roots are exposed but there is plenty of submerged root habitat available. Other habitats are not affected.

17 – Most shallow roots are exposed, but there is plenty of submerged root habitat. Other habitats are not affected.

16 – Some larger rooted areas are partially exposed but there is plenty of submerged root habitat. Other productive habitats are not affected.

**Suboptimal:** Water covers more than 75% of the streambed and less than 25% of productive habitat is exposed.

15 – Some submerged rooted areas are totally exposed although the habitat is still plentiful. Other productive habitats are not affected.

14 – Most root habitat is exposed. Other productive habitats are available.

13 – All root habitat is exposed. Other productive habitats are available.

12 – A second near-shore habitat such as macrophyte beds is partially exposed. Other, mid channel habitats such as fallen trees are available for full colonization.

11 – All near shore habitat is compromised although some is available. Other, mid-channel habitats such as fallen trees are available for full colonization.

**Marginal:** Water covers 25% - 75% of the streambed, and/or productive habitat is mostly exposed.

10 – Water covers about 75% of streambed. All near shore habitat is exposed. Mid channel habitats are available and not affected.

9 – Water covers 60 – 70% of streambed. All near shore habitat is exposed. Some mid channel habitat such as fallen trees and snags are compromised but still available for full colonization.

8 – Water covers about 50% of streambed. Mid channel habitat is compromised but at least one productive habitat is still common.

7 – Water covers 30 – 40% of streambed. Most habitat is exposed, at least one productive habitat is still common.

6 – Water covers about 25% of streambed. Isolated areas of productive habitat.

**Poor:** Very little water in channel and mostly present as standing pools. Little or no productive habitat due to lack of water.

5 – Very little flow evident. Isolated patches of productive habitat.

4 – Very little flow evident. Remaining habitat is un-productive

3 – Water reduced to standing pools. Isolated patches of productive habitat.

2 – Water reduced to standing pools. Remaining habitat is un-productive.

1 – Stream is dry.

**Comment:** Use comment field to explain factors affecting the amount of water in the stream including natural (beaver activity, karst, drought etc.) and unnatural (man-made dams, log jams at bridges, water withdrawal etc). Also use comment field to indicate if there is naturally no productive habitat which would affect ranking within category.

## 6. Channel Alteration

Determine how much, if at all, the stream reach has been altered by man-made activities (not beavers). Channel alteration is present when artificial embankments, riprap, and other forms of artificial bank stabilization or structures are present; when the stream is very straight for

significant distances; when dams, culverts or bridges are present; when dredging or gravel/rock removal is evident, when snags/deadfall is removed, 4-wheel activity has altered the bottom contours/compressed riffles and when other such artificial changes have occurred. Bridges, dams or other man-made structures upstream or downstream of the assessed reach should be considered if they affect flow patterns in the targeted reach.

**Optimal:** Channelization, dredging, or 4-wheel activity (past or present) absent or minimal. Stream has normal meander pattern. Shoring structures including riprap are absent. Artificial structures are not present in stream reach. Bridges, culverts, dams or other structures upstream or downstream are not affecting the stream reach.

20 – Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. There is no evidence of past or present dredging or rock removal. There is no evidence of 4-wheel activity. Stream has normal meander pattern.

19 – Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. Evidence of past rock removal. There is no evidence of gravel/sand dredging or 4-wheel activity. Stream flow pattern and habitat not affected.

18 – Stream has never been channelized and there are no artificial structures in stream reach or within impact area of reach. Evidence of past gravel or sand dredging. There is no evidence of 4-wheel activity. Stream flow pattern and habitat not affected.

17 – Past channel alteration in small area (less than 5% of reach). Stream flow pattern not affected. Modification is stable, well vegetated with natural vegetation, no erosion potential. There are no artificial structures in stream reach or within impact area.

16 – Evidence of recent 4-wheel activity. In-stream habitat, stream contours and banks not affected. Artificial structures may be present outside of the reach but are not affecting the flow patterns, habitat or stream contours within reach.

**Suboptimal:** Channelization, dredging or 4-wheel activity up to 40%. May be longer reach if channelization is historic. Channelization has stabilized and altered flow pattern does not affect colonization. Bridges, culverts, shoring or other artificial structures either within or outside of reach have not affected natural flow patterns.

15 – Historic channelization has stabilized. Modification is stable, well vegetated with natural vegetation and no erosion potential.

14 -- Bridge, culverts, shoring or artificial structures may be present but do not affect natural flow patterns in reach. (Includes structures upstream or downstream as well as within reach.)

13 – Recent off-road vehicle activity in stream. Channel substrate slightly disturbed. Natural stabilization and re-colonization expected.

12 – Evidence of recent rock removal or gravel/sand dredging has had slight impact on reach. Natural stabilization and re-colonization is expected.

11 – New channelization in up to 40% of stream reach. Modification is stable, well vegetated with natural vegetation, no erosion potential. (If not stable score 10.)

**Marginal:** Channelization, dredging or 4-wheel activity 40 - 80% or less amount of channelization that has not stabilized. Bridges, culverts, shoring or other artificial structures either within or outside of reach may have slightly affected natural flow patterns.

10 – Less than 40% of reach altered but has not stabilized.

9 – 40 - 80% of reach has been recently been channelized but is stable with natural vegetation.

8 – Bridge, culverts, shoring or artificial structures have slight affect on natural flow patterns in reach. (Includes structures upstream or downstream as well as within reach.)

7 – Dredging, rock removal, 4-wheeling or other in-stream activity has impacted habitat in 40 - 80% of reach.

6 – 40 - 80% of reach has been altered and has not stabilized.

**Poor:** Over 80% of the stream reach channelized, dredged or affected by 4-wheel activity, instream habitat greatly altered or removed entirely or artificial structures within reach or upstream/downstream of reach have greatly affected natural flow patterns.

5 – Over 80% of the stream reach has recently been channelized but is stable with natural vegetation.

4 – Over 80% of the stream reach is channelized and has been stabilized with artificial shoring.

3 – Over 80% of the stream reach is channelized and has not stabilized.

2 – Impoundment, bridge or other artificial structure has a high level of impact on normal stream flow and/or channel pattern. Include upstream or downstream structures that have substantially affected the sample reach.

1 – At least part of stream reach is in concrete or other artificial channel (including culverts).

**Comment:** Use comment field to indicate type of channel alteration (channelization, man-made dams, 4-wheel activity) and to explain any score adjustments. Also make note if beaver activity has altered stream (this is a natural condition so would score 20 if there are no artificial modifications but needs to be noted).

## 7. Channel Sinuosity

Evaluate the meandering or sinuosity of the stream. A high degree of sinuosity provides diverse habitat for macroinvertebrates and the stream is better able to handle surges when the flow fluctuates due to rain events. **To estimate this parameter, a longer segment or reach than that designated for the sampling should be incorporated into the evaluation. This will vary by site, but should include at least 2 bends. Maps may be used to estimate the sinuosity of larger streams where field evaluations are not practical.**

The amount the meanders increase stream length determines the condition category. The quality of the meander (whether additional macroinvertebrate or habitat is provided) determines the rank.

**Optimal** – The bends in the stream increase the stream length 3-4 times longer than if it was in a straight line.

20 – Stream meander increases stream length more than 4 times longer than a straight line.

19 – Stream meander increases stream length 4 times longer than a straight line.

18 – Stream meander increases stream length 3.5 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

17 – Stream meander increases stream length 3.5 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

16 – Stream meander increases stream length 3 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

**Suboptimal** - The bends in the stream increase the stream length 2-3 times longer than if it was in a straight line.

15 – Stream meander increases stream length 3 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

14 – Stream meander increases stream length 2.5 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

13 – Stream meanders increase stream length 2.5 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

12 – Stream meander increases stream length 2 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

11 – Stream meander increases stream length 2 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

**Marginal** – The bends in the stream increase the stream length 1-2 times longer than if it was in a straight line.

10 – Stream meander increases stream length 2 times longer than a straight line. Bends provide additional macroinvertebrate habitat.

9 – Stream meander increases stream length 1.5 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

8 – Stream meanders increase stream length 1.5 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

7 – Stream meander increases stream length 1 times longer than a straight line. Bends provide productive macroinvertebrate habitat.

6 – Stream meander increases stream length 1 times longer than a straight line. Bends do not provide additional macroinvertebrate habitat.

**Poor** – Channel straight; waterway has been channelized for a long distance.

5 – Straight channel offset by some slight curves which, not meanders, do serve to provide some habitat and some energy dissipation during surges.

4 – Straight channel with more than one slight curve.

3 – Straight channel with a single slight curve.

2 – Straight channel with no curves but some bank indentations providing habitat. (Stable indentations not subject to erosion).

1 – Channel completely straight with no curves or stable indentations.

**Comments:** Use comment field if necessary to describe any other factors that influenced scoring.

## 8. Bank Stability

Determine whether the stream banks are eroded or have the potential for erosion. Steep banks are more likely to collapse and suffer from erosion than are gently sloping banks, and are therefore considered less stable. Signs of instability include crumbling, unvegetated banks, exposed tree roots, slumping and/or exposed soil. Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

**Optimal:** Banks stable, evidence of erosion or bank failure absent or minimal; little potential for future problems, < 5% of the bank affected.

10 – No signs of instability evident. Banks sloping. Little erosion potential.

9 – Some erosion evident or steep banks or some potential for erosion.

**Suboptimal:** Moderately stable, infrequent, small areas of erosion. 5 – 30% of bank in reach has areas of erosion or other signs of instability.

8 – 5 - 15% of bank has areas of healed over erosion.

7 – 5 - 15% of bank has areas of erosion or other signs of instability. Some are not healed over.

6 – 20 - 30% of bank has areas of erosion or other signs of instability. If approaching 30%, score lower if banks are steep.

**Marginal:** Moderately unstable; 30-60% of bank in reach has areas of erosion or other signs of instability; high erosion potential during floods.

5 – 30 - 40% of bank has areas of erosion or other signs of instability. If approaching 40%, score lower if banks are steep.

4 – 40 - 50% of bank has areas of erosion or other signs of instability. If approaching 50%, score lower if banks are steep.

3 – 50 - 60% of bank has areas of erosion or other signs of instability If approaching 60%, score lower if banks are steep or sloughing.

**Poor:** Unstable: many eroded areas; raw areas frequent along straight sections and bends; obvious bank sloughing; Over 60% of banks has areas of erosion or other signs of instability.

2 – 60 - 75% of bank has areas of erosion or other signs of instability.

1 – 80 - 90% of bank has areas of erosion or other signs of instability.

0 – There are no stable areas on bank.

**Comment:** Use comment field if needed to describe additional factors affecting scoring.

## 9. Bank Vegetative Protection

Determine the type and quality of vegetation on the stream bank. This is the area from the base of the bank to the top of the bank. The object is to determine the ability of the bank to resist erosion as well as the ability of the plants to uptake nutrients, control instream scouring, supply food to shredders and provide stream shading. Streams that have various classes of native vegetation providing full natural plant growth including groundcover, shrubs, understory trees and mature trees will score highest.

In some regions, the introduction of exotics, such as kudzu or privet, has virtually replaced all native vegetation. Although exotics may provide erosion control, they do not provide ideal food and habitat to stream organisms that have evolved to utilize native species. Banks that are dominated by non-native vegetation should score lower. A list of commonly encountered non-native species can be found in Appendix B. Species information and links to county distribution and field guides can be found at [http://www.tneppc.org/Invasive\\_Exotic\\_Plant\\_List/The\\_List-by\\_habit.htm](http://www.tneppc.org/Invasive_Exotic_Plant_List/The_List-by_habit.htm)

Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

Condition category is determined by estimating the amount of bank covered by **undisturbed native vegetation**. Rank is determined by complexity of vegetation type.

**Optimal:** More than 90% of the streambank surfaces and immediate riparian zone covered by undisturbed vegetation. All four classes (mature trees, understory trees, shrubs, groundcover) are represented. All plants allowed to grow naturally. All plants are native.

10 - No disruption. All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are represented and allowed to grow naturally.

9 - Minimal disruption affecting less than 10% of stream bank. All classes of vegetation are represented and allowed to grow naturally.

**Suboptimal:** The majority (70 - 90%) of the bank is covered by undisturbed native vegetation. One class may not be not well represented. Disruption evident but not affecting full plant growth. Non-native vegetation may be present but rare (< 30%).

8 – Over 90% of bank area covered by native vegetation but one class not well represented.

7 – 70-90% of bank area covered by native vegetation. All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are well represented and allowed to grow to full height.

6 – 70 - 90% of bank area covered by native vegetation but one class not well represented. Other classes allowed to grow to full height.

**Marginal:** 50 - 70% of the bank covered by undisturbed vegetation. Non-native vegetation may be common (30 - 50%). Two classes of vegetation may not be well represented.

5 – All classes of vegetation (mature trees, understory trees, shrubs, groundcover) are represented. If approaching 70% score suboptimal 7 if all vegetation allowed to grow to full height.

4 – One class of vegetation not well represented or not allowed to grow to full height. If approaching 70% score suboptimal 6 if all vegetation is native and allowed to grow to full height.

3 – Two classes of vegetation not well represented or not allowed to grow to full height or non-native vegetation is common.

**Poor:** Less than 50% of the bank is covered by undisturbed vegetation or more than two classes of vegetation are not well represented or most vegetation has been cropped. Non-native vegetation may be dominant (> 50%).

2 – Vegetation that is present is mostly native and allowed to grow to full height.

1 – Most vegetation is not allowed to grow to full height or is non-native.

0 – Bank vegetation is absent or too sparse to provide bank protection or habitat.

**Comment:** Use the comment field to describe what class of plants are missing and/or describe exotic plants.

## 10. Riparian Vegetative Zone Width

Estimate the width of natural vegetation from the top of the stream bank out through the riparian zone (approximately 18 meters). Disturbance to the riparian zone occurs when there are roads, parking lots, fields, row crops, lawns, parks, bare soil, buildings, logging, campgrounds, golf courses or other human activity.

Each bank is evaluated separately on a scale of 0 to 10 and the cumulative score of both banks is used for this parameter. Left and right banks are determined by facing downstream.

Condition category is determined by estimating the width of the riparian zone from the top of the stream bank, outward. Generally the riparian ends at first indication of human disturbance with the exception of un-paved footpaths or trails in an otherwise undisturbed riparian.

Scoring within the category should be based on the level of impact the disturbance has. For example un-grazed fields would score higher than active fields. Lawns would score higher than paved areas.

Paths, and walkways in an otherwise undisturbed riparian zone may be judged to be minimal disturbance if they are narrow, unpaved and show no evidence of erosion. They should not affect condition category, but should lower score one point within category.

**Optimal:** Average width of riparian > 18 meters throughout reach.

10 – There is no human disturbance.

9 – Human disturbance minimal, for example, an un-paved footpath.

**Sub-optimal:** Average width of riparian 12 – 18 meters throughout reach.

8 – Human disturbance, after 12 meters of undisturbed riparian is minimal, for example an un-grazed hay field or areas of riparian that are less than 18 meters are small.

7 – Human disturbance, after 12 meters is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.

6 – Human disturbance, after 12 meters is not vegetated, for example paved or gravel lots, roads, bare dirt.

**Marginal:** Average width of riparian 6 – 11 meters throughout reach.

5 – Human disturbance, after 6 meters of undisturbed riparian is minimal, for example an un-grazed field, or areas that are less than 12 meters are small.

4 – Human disturbance, after 6 meters is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.

3 – Human disturbance, after 6 meters is not vegetated, for example paved or gravel lots, roads, bare dirt.

**Poor:** Average width of riparian < 6 meters throughout reach.

- 2 – Human disturbance is minimal, for example an un-grazed field or areas that are less than 6 meters are small.
- 1 – Human disturbance is vegetated but has frequent use or is close cropped. For example lawns, golf-courses, row crops, active pasture.
- 0 – Human disturbance has removed all vegetation, for example paved or gravel lots, roads, bare dirt.

**Comment field:** Indicate type of disturbance and any additional factors affecting score.

### **Scoring**

Total the 10 habitat parameters and compare the score to the Habitat Assessment Guidelines (Table 2) to determine whether the habitat is capable of supporting a healthy benthic community (not impaired). Note that habitat scores in four ecoregions (68a, 68c, 69d and 69e) vary by season. Indicate at bottom of field sheet if total habitat score is above (not impaired) or below (impaired) ecoregional guidelines in blank provided. If score is low indicate whether this is a result of natural conditions (such as drought or beaver activity) or is the result of human disturbance. Write a brief description in space provided. (If more room is needed attach another sheet).

Sometimes it may be useful to evaluate individual parameters in addition to the total habitat score. For example even if the total habitat score meets regional guidelines, the individual parameters of embeddedness and sediment deposition may be low indicating a problem with sedimentation. Likewise, there may be a problem with riparian removal even though habitat scores meet regional guidelines. On the other hand, a low total score may not indicate a habitat problem if the channel flow status and velocity depth regime score low in a region where reference streams have extremely reduced flow during the summer and fall. Appendix A provides ecoregion specific expectations for each parameter on the Habitat guidelines field sheet.

**Table 2: Habitat Assessment Guidelines**

| Ecoregion | Habitat Field sheet | Season      | Streams > 2 sq mile drainage | Headwater streams ≤ 2 square mile drainage |
|-----------|---------------------|-------------|------------------------------|--|
|           |                     |             | Not Impaired                 | Not impaired                               |
| 65a       | Low Grad.           | Jan. – Dec. | ≥ 118                        | ≥ 115                                      |

| 74b       | Low Grad.           | Jan. – Dec. | ≥ 111                        | ≥ 113                                      |

## **Protocol E: Stream Survey Field sheet**

### **Biologist/Environmental Specialist**

The stream survey field sheet must be completed when macroinvertebrate surveys are done (Appendix B). Information on the field sheet is designed to help make assessment decisions and provide supplemental information for interpreting biological sample results. Add additional information, not included on the field sheet, as needed. Only use the version provided in Appendix B. Earlier versions should no longer be used. Consult all personnel present during sampling for additional observations that may have been overlooked before leaving the site. It is recommended that the field sheet be copied on waterproof paper.

#### 1. Stream Survey Information

Complete all information in this section. Lat/long does not need to be completed on existing sites provided the rest of the information is in the water quality database.

- a. **Station ID** as already assigned in Water Quality Database or following protocol B for new stations. (Do not rely on memory or assume no-one else has ever collected any type of sample at this location. TVA or a permit holder may already have a station at this location and a TDEC station ID has been established. Often, a site was collected by another team from the same field office or several years ago. It is important that consistent IDs be used for all data associated with a site no matter who collected it.)
- b. **Stream Name** based on 24K scale topographic map or GIS layer.
- c. **Station Location.** If it is an existing station, use location in current stations table of the water quality database. If it is a new station, use streams names or features identifiable on topographic map if possible. However be specific enough so that someone else can find the sampling location.
- d. **County** is the county name where the station is located (even if most of drainage is in another county). For streams which form county boundaries, be consistent with other stations located on the stream.
- e. **WBID#/HUC:** When possible use Water Body ID Number (WBID#) assigned for the stream segment as assigned in the Assessment Database (ADB). Otherwise indicate 8 digit HUC code.
- f. **Latitude and Longitude** are to be recorded in decimal degrees measured by GPS. If it is a new site, the latitude and longitude will be recorded mid-stream in the middle of the sampling reach with a calibrated GPS. Always check latitude and longitude against the database for existing stations to verify location. If discrepancies are discovered, notify PAS of need to correct database information once you have confirmed you are in the correct location and GPS reading are accurate.
- g. **Assessors:** Include full name (initials may be used on subsequent pages). Include agency if not WPC.
- h. **Date:** Record date in mm/dd/yy format.
- i. **Time:** Indicate time of arrival at site in 24 hour clock (military time)

- j. **Stream order:** Strahler order based on 24 scale topographic map or GIS layer. Do not use Gazetteer. This is necessary to know what biometrics ranges to use for scoring. (To save time >2 can be entered for larger streams).
  - k. **RM:** River mile should be indicated if not included in station ID (example reference streams).
  - l. **Drainage area:** Square mile drainage upstream of sampling location. Necessary in headwater streams (first or second order) to determine appropriate bioecon guidelines or biocriteria to use. Optional in larger streams. Drainage area can be quickly determined using the interactive map at <http://water.usgs.gov/osw/streamstats/tennessee.html>
  - m. **Watershed Group #:** Indicate watershed group based on cycle. This is especially important in watersheds split into 2 cycles such as 06060102, 06020001 and 06010201.
  - n. **Ecoregion:** The ecoregion can be determined by locating the sample location at <http://tnmap.tn.gov/wpc/> (make sure the ecoregion layer is checked). If the upstream drainage is in another ecoregion record this in U/S ECO. Contact PAS if uncertain of ecoregion.
  - o. **TOPO:** Optional, indicate topographic map where station is located.
  - p. **Gaz. Page:** Optional, indicate gazetteer page where station is located.
  - q. **Drainage Basin:** Optional indicate drainage basin where station is located.
  - r. **Project/Purpose:** Circle the appropriate reason for collecting sample or indicate reason in "other" slot.
2. Samples Collected.

Document EFO log number for each biological sample type collected. If chemical or bacteriological samples were collected at the same time, circle the appropriate parameters.

3. Field Measurements

Use calibrated meters for all field measurements (protocol C)

Designate what type of meter (and which meter) was used to make readings. The measurements for each parameter (including duplicates) are recorded in the appropriate boxes. All measurements are recorded in the units specified on the field sheet. Record any other field measurements, such as percent oxygen saturation, turbidity or TDS that were taken at the time of sampling (include units). Also record field measurements on the chemical request forms if chemical samples are being collected at the same time. (Average

duplicate readings on the chemical request forms since only one value can be entered in the laboratory's system).

If, after the drift check, the meter was found to be off by more than 0.2 units for pH, temperature or dissolved oxygen (or more than 10% for conductivity or percent saturation), write an N before the measurement on the stream survey field sheet for all sites visited between the initial calibration and the drift check. The N designates questionable readings. Also, put an N before readings on the chemical request form. If the chemical request form has already been turned into the laboratory, fax the field sheet to the central office. This will insure the readings are flagged as questionable when they are entered into the water quality database.

Indicate any problems with the meters that would lead to questionable measurements. This line should be filled in anytime measurements are unusual even if it is only to verify that measurements are accurate.

Circle the appropriate level of precipitation for the previous 48 hours (or circle unknown). Also, indicate the ambient weather and record approximate air temperature.

#### 4. Watershed Characteristics

Drive or walk as much of the upstream watershed as possible. Indicate the approximate percent of the watershed observed. Note the prevalent land-use in the watershed upstream of the sampling location in the spaces provided, estimating percentages. Record any other land uses that, although not dominant, may potentially affect water quality. These direct observations can be supplemented by land use information found in some of the recently developed TMDL/modeling tools and GIS systems. However, it should be noted that much of the land-use imagery is dated and ground-truthing is preferable when practical.

#### 5. Physical Stream Characteristics

- a. These observations apply to the land use surrounding the sampled stream reach. Indicate the length of the stream reach sampled in meters.
- b. Observe and note the surrounding land use in the immediate stream reach for each bank. Use blank field to record any additional land use.
- c. Indicate the magnitude of observed human disturbance to the stream. Describe any others not listed.
- d. Canopy cover should be measured using a spherical densiometer mid-stream midway of the area(s) where biological samples were collected (mid-riffle if collecting one riffle, midway between two riffles if collecting multiple riffles, mid-distance between most upstream and most downstream bank sample if collecting bank jabs). The densiometer

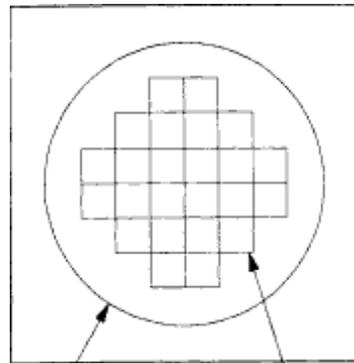

is a convex mirror etched into 24 ¼-inch boxes (Figure 8). Each box is subdivided into four smaller squares, via an imaginary dot in the center of the box, to create a total of 96 smaller squares that can be counted within the entire densiometer. Hold the densiometer one foot above the water surface. Holding the instrument at this level eliminates errors due to differing heights of samplers and different water depths, and includes low overhanging vegetation more consistently than holding the densiometer at waist level. Take four measurements, facing upstream, downstream, the right descending bank, and the left descending bank. Hold the instrument far enough away from the body so that the operator's head is just outside the grid. Count the number of small squares (out of a total of 96) that have tree canopy. Record this number (number of dots **WITH** canopy cover) on the field sheet. In order to get the overall percent canopy cover for that point, sum the four measurements and divide the total by 384 and multiply by 100%. Record this number in the measured field.

In addition to the measured canopy taken at mid sample point, estimate the canopy cover for the entire reach. Either circle the appropriate category or record a number in the estimated field.

Note: If also collecting periphyton, the densiometer measurements from the five transects recorded on the periphyton worksheet will take the place of these measurements.

*Photo provided by Joellyn Brazille, Memphis EFO*

*Cook et al. 1995*

### **Figure 8: Spherical Densiometer**

- e. Note any sediment deposits, type of sediment and water turbidity. Indicate the water color if not clear.
- f. Note any substance that may be causing a surface sheen or foam including bacteria, nutrients or surfactants.
- g. Record the estimated abundance and type of algae present. (Indicate if a periphyton survey was performed).

- h. Estimate the average depth, width and length (in meters) of a typical riffle, run and pool within the survey reach. (Indicate if actual measurements are taken.)
- i. Flow measurements are not required for biological surveys unless chemical samples were collected at the same time. However, if flow measurements were taken or if a staff gauge is available, record the calculated flow.
- j. Record the high water mark and bank height in meters.
- k. Circle the flow conditions, gradient and stream width that best describes the sample reach.
- l. Estimate the percent contribution of each substrate type in riffles, runs and pools

6. Field Based Assessment

- a. If biorecon was collected, record score. Indicate taxonomic level.
- b. If SQSH was not collected and assessment is based on biorecon and field observations, indicate whether benthic community appears impaired
- c. Describe basis for determination if based on biorecon. If supporting, indicate observations that led to this conclusion. If impaired, describe observations that led to this conclusion, for example low abundance of EPT. Include observed impacts and possible sources.
- d. Describe any other conditions observed at the time of sampling (additional pages are to be used if necessary). Include any changes observed from previous sampling efforts. Note directions to the site and any special permission or keys needed for access. Note anything special or unusual that would assist in assessments. Ask other team members for input. Take care not to contradict information provided on other parts of the sheet or on the habitat field sheet, for example sedimentation, erosion and algae observations.
- e. A photographic record is to be kept on each sampling station. Digital photographs are preferred. Photographs of the general stream condition and potential pollution sources should be taken during the original sample visit. Photographs of any changes are taken during subsequent sampling trips. Document the picture identification and a brief description on the field sheet.
- f. Stream Sketch - A station sketch is made at the time of sampling. This sketch should be detailed enough so that subsequent sampling teams or data reviewers can determine where samples were taken and what potential sources of impairment were present. Use a separate sheet of paper if necessary. At a minimum, the sketch should include a rough outline of stream sinuosity, direction of flow, location of riffles and pools, location of samples (benthic, chemical, field parameters), location of bridges or any other man-made

structures (include distance from sampling point), location of tributaries, run-off ditches, discharges, livestock access, and any other potential pollution sources. It is helpful to designate which direction is north.

Note: A small table is provided in this section for those who wish to transcribe biorecon and habitat information from other field sheets. This information is not required since it is included elsewhere. If using this feature, make sure that information matches both the biorecon and habitat field sheets and that any later changes or corrections are made on all sheets.

## **Protocol F - Biorecon (Reconnaissance/Screening)**

### **Biologist/Environmental Specialist with expertise in macroinvertebrate taxonomy**

Because the biorecon is qualitative and involves limited data generation, its effectiveness depends largely on the experience of the biologist performing the assessment. The biologist should have stream assessment experience, knowledge of aquatic ecology and expertise in benthic macroinvertebrate taxonomy and community structure for the ecoregion in which they are conducting the assessment.

The Biorecon method is based on EPA's *Rapid Bioassessment for Use in Wadeable Streams and Rivers* (Barbour et. al., 1999).

This method is a standardized screening tool useful for problem identification and/or prioritizing sites for further assessment, monitoring or protection. As specified in the EPA document, it is designed to be expedient and requires an experienced and well trained biologist to be effective. It is most useful in discriminating clearly impaired or non-impaired areas from those areas requiring further investigation. However, chemical samples, in-stream water quality measurements, field observations, professional expertise, estimates of taxa abundance, identification to a lower taxonomic level and/or habitat data can help clarify assessment decisions in ambiguous situations. Biorecons cannot be compared to biocriteria or to semi-quantitative samples. Only qualitative metrics which do not include relative abundance can be calculated. However, metrics may be compared to the biorecon guidance derived from biorecons conducted at ecoregion reference sites (Tables 4 and 5).

**The flow charts in Protocol A should be used when determining when biorecon sampling is appropriate.**

#### 1. Biorecon Field Sheet Header

Complete all header information on biorecon field sheet (Appendix B). See protocol E for completion of Station ID, Stream Name, Station Location, HUC, Group, Assessors, Date, Time, Ecoregion, U/S ecoregion, Order, Drainage Area. See protocol H for assigning log number. (A log number must be assigned even if a voucher is not collected for database entry and tracking).

If this is a QA/QC sample, circle the appropriate type(s): Duplicate sample, pick efficiency, ID verification (note that ID verification is confirmation of identification by a second taxonomist, not the initial identification of voucher specimens). Include date and initials of taxonomist for any vouchers that have been identified in the space provided.

#### 2. Taxonomic Level

Unless this is an ecoregion or headwater reference site, either genus level or family level biorecons can be conducted. (Both genus and family must be reported at reference sites).

Genus level biorecons are more sensitive but require more time and taxonomic expertise. Often family level biorecons are adequate screening tools. If more sensitivity is needed, a semi-quantitative sample may be more useful than a genus level biorecon. It is important that taxonomic level is consistent. For example all taxa (except chironomids, oligochaetes, acarina, nematodes, and nematomorphs) should be identified to genus and the genus guidelines used or all taxa should be identified to family and the family guidelines used.

### 3. Habitat Selection

Determine what habitat is available and the relative percent contribution of each habitat. Record percent habitat on the biorecon field sheet (even for those not sampled).

Select 1 to 4 of the most productive habitats for sampling. Only consider habitats that comprise more than 5% of the stable habitat in the stream -reach. Productive habitats include riffles, run or pool rocks, leaf packs, woody debris, rooted undercut banks, macrophyte beds, and fine sediment. Other productive habitats that comprise more than 5% of the stream reach may also be selected. Estimate approximately 0.5 meters of sampling area for any habitat selected.

Proportion the selected habitats into four portions based on percent contribution. For example, if the selected habitats are riffle (50%), leaf packs (30%) and undercut banks (20%) the sample would be comprised of two riffle kicks, one leaf jab and one bank jab. Never collect more than four portions. Record the the number of jabs collected in each habitat on the Biorecon Field Sheet.

### 4. Sample Collection

Sample selected habitats using a 500 micron mesh triangular or dip net. Use a combination of kick and/or jab techniques depending on the type of habitat. A single jab consists of thrusting the net into a productive habitat for a linear distance of 0.5 meter (approximately two net widths). A kick is a stationary sample accomplished by positioning the net and disturbing the upstream substrate for a distance of 0.5 meter. Take care not to over-sample since this could skew results as reference data is calibrated to 4 jabs from a maximum of 4 habitats.

#### a. Riffle Kick:

Position the net on the bottom of the stream and disturb the substrate by shuffling and kicking your feet the width of the net and for approximately 0.5 meter upstream of the net. Use hands or soft brush to scrape clinging organisms off larger rocks.

b. Run or Pool Rock:

Select several rocks of various sizes equaling approximately 0.5 square meters of surface area in run or pool areas. (Note these are separate habitats.) Avoid rocks that are embedded.

c. Leaf Packs:

Collect three handfuls of leaf packs by positioning the net downstream or under the leaf pack, then scooping the leaves into the net by hand. Select leaf packs from various locations (riffle, run, and pool if possible). The leaves should be submerged and show evidence of being consumed by benthic macroinvertebrates (50% decomposition is optimal). Avoid collecting recently deposited or fully decomposed leaf litter.

d. Snags/Woody debris:

Select snags and other woody debris that have been submerged for a relatively long period (not recent deadfall). Sample submerged woody debris by jabbing in medium-sized snag material (sticks and branches). The snag habitat may be kicked first to help dislodge organisms, after placing the net downstream of the snag. Accumulated woody material in pool areas are also considered snag habitat. A single jab is approximately two net widths or three handfuls of loose material.

e. Undercut Banks or Tree Roots

Select bank habitat that is undercut with submerged hanging roots or plants. Submerged tree roots that are not undercut may also be sampled (this constitutes a different habitat type). Thrust the net vigorously under the bank to dislodge clinging organisms. A single jab is approximately two net widths. Avoid digging into the sediment, as this constitutes another habitat type.

f. Macrophytes

In deep water, sample aquatic plants that are rooted on the bottom of the stream by drawing the net through the vegetation from the bottom to the surface of the water. In shallow water, bump or jab the net along the bottom in the rooted area. Avoid collecting sediment if possible. Either type of macrophyte jab should not exceed 0.5 linear meters (two net widths).

g. Fine sediment

Sediment is found in quiet areas of the stream. Select fine silt, sand or muck with minimal gravel. Seek areas with evidence of tunneling by burrowing

macroinvertebrates. Gently scoop the net through the sediment for 0.5 meters length and approximately 4 cm deep.

## 5. Sample Sorting/Identification

Composite the four jabs in a 500-micron sieve (or the net). Examine large materials (rocks, leaves, sticks) for organisms and then discard. Rinse the remainder of the debris using sieved water in the sieve (or swish the net in the creek). Transfer small amounts of debris to a white pan with a little sieved stream water for field sorting. Keep the rest of the sample submerged. Scan the debris and water for organisms. If doing a **family biorecon**, record field identification (or description for later identification at field office if uncertain.) Unless this is a QC site or identification is uncertain, vouchers do not need to be routinely collected for family biorecons. Vouchers of any families where ID is uncertain and complete vouchers of all taxa at 10% of sites must be collected. Vouchers should also be collected if there is a possibility that more definitive (genus level) identification may be necessary.

If it is a genus level biorecon, record field identification or description of each distinct taxon on the biorecon field sheet (so that you can recognize it back at the office). Voucher specimens of each unique taxon are required for genus level identifications. Any taxa not found on the Tennessee taxa list (Appendix C) must be sent to the lab for expert verification and inclusion in state reference collection.

On the biorecon field sheet for both family and genus biorecons, record the relative abundance of each taxon (rare, common, abundant, dominant). This will help with determination of impairment in ambiguous biorecons. Indicate relative abundance for both field identification and voucher identification (if collected) in the appropriate boxes for each taxon on the biorecon field sheet. If, after voucher identification, relative abundance cannot be estimated (for example multiple taxa were identified that were not differentiated in the field), place an x in the voucher box for that taxon.

1 = rare (1-3 organisms)

2 = common (4-9 organisms)

3 = abundant (10-49 organisms)

4 = dominate (> 50 organisms)

x = uncertain (used to indicate voucher identification with uncertain abundance)

## 6. Voucher Specimens

- a. Family level biorecons. Vouchers (of all taxa in sample) are only required at 10% of sites and any taxon where family cannot be field differentiated (for example Leuctridae/Capniidae; Leptohyphidae/Caenidae; Polymitarcyidae/Ephemeroidea; Baetidae/Ameletidae; Corduliidae/Libellulidae; Psychomyiidae/Polycentropodidae; Unenoidae/Limnephilidae/Odontoceridae; or early instars).

in case further identification is needed at a later date. Add the name of the taxonomist, log number and date identified to the existing internal and external field tags (Figure 11).

|--|

**Figure 11: Example of internal tag after sample identification**

Any genera identified, that are not on the verified taxa list in Appendix E should be sent to the TDH lab for verification and inclusion in the statewide reference collection.

7. **Biometric Calculation** – After confirming field identifications, calculate three qualitative biometrics (that do not rely on relative abundance). Do not calculate NCBI or any other metric that is not qualitative. Never include exuvia, empty caddis cases or empty mollusk shells when calculating biometrics although these can be noted for additional information.

Record metric values, score and total score for either family or genus (or both if reference site) on the biorecon field sheet.

- a. **Taxa Richness (TR)** – The total number of distinct taxa found at a site. Do not include empty caddis cases, empty mollusk shells, exuvia, non-aquatics or winged adults. Do not count unidentified genera as a separate taxon, unless they are clearly a different genus (or family) than those identified. When counting chironomid taxa for family level biorecons, all chironomids are counted as a single family, when counting chironomids at genus level, red midges, non-red midges and tanypodinae are counted separately for a maximum total of three genera. Chironomids should be categorized in the field and there is no need to collect vouchers since they will lose color. Otherwise Chironomini will be counted as red midges. Orthocladinae, Diamesinae and Tanytarsini will be counted as non-red midges.
- b. **EPT** – The total number of distinct EPT taxa found at the site. (Do not include empty caddis cases, exuvia, non-aquatics or winged adults). Do not count unidentified genera as a separate taxon, unless they are clearly a different genus (or family) than those identified.
- c. **Intolerant Taxa (IT)** – The number of intolerant taxa (defined as having an NCBI value from 0.00 to 3.00) found at the site. Appendix C contains a list of families that should be counted as intolerant. For statewide consistency and comparability to the reference database, DO NOT count any animals intolerant that are not on this list.

When doing genus level biorecons, if an animal can only be identified to family and there are no other genera present in that family, it should be considered intolerant if it is an intolerant family. Likewise, for new genera where a tolerance value has not been assigned, it will be considered an intolerant taxa if the family is tolerant (see protocol k for assigning NCBI values).

**NOTE:** Although the biorecon procedure calls for relative abundance to be estimated in the field, these numbers cannot be used for any metric calculations since they are not collected or subsampled in a quantitative manner. This information can be used less formally to evaluate the health of the macroinvertebrate community especially in the case of ambiguous scores. For example, if the number of EPT taxa is high, but only a few individuals were found, it may be indicative of stress in the community.

8. Assessment Guidelines – Determine the value (1, 3, or 5) for each metric based on ranges at either the family (Table 3) and/or genus (Table 4) level. Add the three values together. Determine the assessment based on the total score (page 10). Do not use the family score if organisms were identified to genus level. The genus level provides a more accurate assessment and may not agree with the family level guidance. Keep the following information in mind when assessing biorecon data:
  - a. Biorecons are most useful in areas of clear impairment or in areas that are not impaired. Sites that fall in the middle range (7 – 9) may be too ambiguous to make assessments using the biorecon technique. These sites may require a more intensive assessment method. A Semi-Quantitative Single Habitat Sample (SQKICK or SQBANK) can be collected for clarification of use support (Protocol G). Chemical samples, in-stream water quality measurements, field observations, professional judgment and habitat data may also help clarify assessment decisions.
  - b. Preliminary guidelines have been developed for headwater (< 2 sq mile) drainage in some bioregions. In other bioregions an upstream, watershed or ecoregional reference must be collected at the same time for comparison to test sites.
  - c. Comparisons to the ecoregion reference guidelines are not appropriate at sites whose upstream watershed has drainage of more than 20% in another bioregion. Data should be scored using both bioregions. If scores disagree, professional judgment should be used to make assessment.

**Table 3: Assessment Guidance for Family Level Biorecons.**

| Bio-region | Season   | Drainage area *<br>(sq miles) | Taxa Richness (TR) |       |      | EPT  |      |     | Intolerant Taxa (IT) |     |     |

\* Caution should be used in streams ≤ 2 square mile drainage

\*\* It is recommended that biorecons not be used in ecoregion 73 since the intolerant richness metric is not applicable.

### **Score Interpretation for family and genus level biorecons:**

#### **For all bioregions except 73ab:**

11-15 = Non-impaired (Supporting)

6-10 = Ambiguous (Need Additional Data)

$\leq 5$  = Severely Impaired (Partially or Not-Supporting)

#### **For bioregion 73ab:**

7-10 = Non-impaired (Supporting)

3-6 = Ambiguous (Need Additional Data)

$\leq 2$  = Severely Impaired (Partially or Not Supporting)

### **Scoring for headwater streams for ecoregions not included in Tables 3 or 4:**

In headwater streams where an ecoregion reference score has not been calculated, it will be necessary to sample a reference site at the same time. A reference will also need to be collected in atypical streams that are not directly comparable to reference guidelines. Ideally this will be an ecoregion reference. Otherwise an upstream or watershed reference should be used. In order to compare sites trisect the reference value for each metric (taxa richness, EPT richness and intolerant taxa):

Score 5 > One less than [metric value – (metric value/3)]

Score 3 < lowest score 5 – (metric value/3) to one less than lowest score 5

Score 1 < lowest score 3

For example, in ecoregion 68b insufficient samples have been collected to calculate headwater reference guidelines. So, if an assessment needed to be conducted on a reference stream in 68b using a biorecon, a reference sample would be collected at the same time.

To calculate the reference-based scoring for family richness, if the number of distinct families at the reference site were 20:

Score 5 would be  $\geq 20 - (20/3)$  which is 13

Since 13 distinct families is the lowest number that would score a 5, in order to calculate the range for a score of 3 would be  $< 13 - (13/3)$  to 13 (or 9 to 12)

Since 9 is the lowest number of families that would score a 3, in order to calculate a range for a score of 1 would be  $< 9$

The same procedure would be used to calculate the scoring ranges for EPT richness and intolerant richness or for genus level.

## **Protocol G – Field Collection Techniques for Semi-Quantitative Single Habitat Sample (SQKICK or SQBANK)**

### **Biologist or Environmental Specialist**

Collect a semi-quantitative single habitat sample (SQKICK or SQBANK) when a quantifiable assessment of the benthic community is needed. **See flow charts Protocol A for guidance.** This method is directly comparable to the Division's numeric translators for biocriteria. This is a more defensible and sensitive method than the biorecon. When both sample types have been collected, semi-quantitative sample results will take precedence over biorecon results.

The semi-quantitative single habitat sample will generally be used for:

- a. 303(d) list removal or addition (a biorecon can be used if it shows the site clearly supporting or non-supporting)
- b. Nutrient TMDLs
- c. Permit compliance and enforcement
- d. Exceptional Tennessee Water designation for exceptional biological diversity.
- e. Pre/post BMP or ARAP
- f. CADDIS analysis
- g. Trend Analysis
- h. Ecoregion or headwater reference sites (along with genus level biorecon)
- i. Confirmation of ambiguous biorecons.
- j. Any study that has the potential of being used by the Water Quality Control Board.

In order for the data to be compared to the reference database:

- a. Samples must be collected in the exact manner outlined in this section.
- b. The upstream watershed must be 80% within the bioregion.
- c. The stream size must be comparable to those in the reference database for that bioregion (Appendix A).

There are three methods of semi-quantitative sample collection:

- a. SQKICK (Riffle streams larger than 1 meter wide)
- b. Modified SQKICK (Riffle streams less than 1 meter wide or too shallow for the 1 meter kick net)
- c. SQBANK (Non-riffle streams)

The type of sample collected will depend on the stream type and/or ecological subregion. Ecoregions can be determined for specific stream segments by using Tennessee's Online Water Quality Assessment Database (<http://tnmap.tn.gov/wpc/>). Contact the Planning and Standards section if there is uncertainty about what ecoregion a stream is located in.

a. **Semi-quantitative Riffle Kick (SQKICK)**

Collect a semi-quantitative riffle kick (SQKICK) in ecological subregions 65j, 66d, 66e, 66f, 66g, 67f, 67g, 67h, 67i, 68a, 68b, 68c, 69d, 71e, 71f, 71g, 71h, 74a, and riffle streams in 71i. If a riffle is not present, a semi-quantitative bank sample can be collected, but will not be directly comparable to the reference criteria. Therefore, an upstream or off-site reference SQBANK will also need to be collected (this can be a bank sample collected at one or more of the established ecoregion reference sites). If riffles have been compromised by sedimentation or are embedded, they should still be sampled since impacts are being measured. For small (< 1 meter wide) or shallow streams, the modified kick method (protocol, see b, should be used).

1. Use a (two-person) one square meter kick net with a 500-micron mesh to sample the riffle. If necessary, use rocks to weight the bottom edge to prevent the flow of water beneath the net. At each site, collect two kicks: one from an area of fast current velocity and one from an area of slower current velocity. Always collect the downstream sample first. Avoid areas with large leaf packs caught on the rocks if possible. If the stream is too small to do two riffle kicks in a single riffle, sample two separate riffles. (In extremely small or shallow streams, sample 4 riffles using the modified SQKICK for small streams – method b.)
2. One biologist holds the net at an angle that allows the current to flow into it making sure the bottom is in contact with the substrate and the top of the net is above the surface of the water. The net should have the maximum wetted area by laying it back as far as possible, while keeping the top of the net above the surface of the water. The second biologist disturbs the substrate for approximately one-meter distance and the width of the net (one meter) upstream of the net by kicking and shuffling the substrate. This causes organisms and debris to flow into the net. Larger rocks may be lifted and rubbed with the hands or a soft brush to remove clinging organisms.
3. Once the kick is completed, allow time for the lighter debris to finish floating into the net. The biologist who performed the kick then grabs the two pole ends at the bottom of the net and carefully lifts the net out of the water while the other biologist continues to hold the upper end making sure the top of the net does not dip below the water surface allowing organisms to escape. If the top of the net dips under the water and debris flows out, discard the sample and collect another kick. Carry the net horizontally to the bank for processing.
4. Composite the debris from both kicks. Carefully position the net in a 500 micron sieve bucket. Rinse debris and organisms, with sieved water, off the net into the sieve bucket. Make sure to get all debris and organisms. Thoroughly rinse the sample using sieved water to remove fine sediment. Large rocks or organic material, such as whole leaves or twigs, are discarded after rinsing and removing clinging organisms. Transfer the sample to a wide mouth or plastic container. Using forceps, remove all organisms clinging to the net

and add them to the sample container. If upon cursory examination of the debris, it does not appear that a minimum of 200 organisms have been collected after 2 kicks, perform additional kicks in the same reach until at least 200 organisms are assured. Document the number and location of kicks on the stream survey field sheet and write the number of kicks on the sample tag. If all riffle habitat is exhausted before 200 organisms are collected, document on the stream survey field sheet. Note that samples where more than 2 kicks are necessary to find 200 organisms will be evaluated with extra caution regardless of score.

5. Preserve the sample with 80% ethanol. Note that if a large amount of debris is present in the sample, 90% or stronger ethanol should be used. Include an internal tag (written in pencil on water-proof paper) with the station ID, date, sampler's initials and sample type inside the container with the debris (Figure 7). Attach an external sample tag to the outside of the container. Standard external tags for both biological and chemical samples are obtained from the state lab (Figure 8). Instead of an external tag, the site information can be printed in indelible ink (i.e. Sharpie) on the sample lid. The external tag information must include the Station ID, Stream name, location, sampler's initials, date sampled, time sampled and sample type (Figure 12). A biological sample request form, including chain of custody, must be completed prior to delivery to the state lab for identification (Appendix B).

Figure 12: Example of external tag information (on sample lid)

**b. Modified SQKICK (small and/or shallow streams)**

1. In extremely small streams, where riffles are less than one meter wide, or in those that are too shallow to use a 1 meter kick net, collect a one person stationary kick using an 18-inch single handle rectangular net with a 500-micron mesh.
2. Sample four separate riffles. Starting with a downstream riffle, hold the net perpendicular to the flow making certain the bottom of the net is in contact with the substrate at all times. Disturb the substrate upstream of the net for an area approximately 18 inches long and the width of the net. Do not allow the net to move during the kick as it might cause organisms to drift under the net. Once the kick is complete, allow time for all debris to finish flowing into the net.
3. Composite the debris from all four kicks. Use forceps, to remove all organisms clinging to the net and add them to the debris. Thoroughly rinse the sample using sieved water to remove fine sediment. Large rocks or organic material such as whole leaves or twigs, are discarded after rinsing and removing clinging organisms. If upon cursory examination of the debris, it does not appear that 200 organisms are in the composited sample, collect additional kicks and add them to the composite. If all riffle habitat is exhausted before 200 organisms are collected, document on the stream survey field sheet. Document the total number of kicks on the sample tag and on the stream survey field sheet.
4. Place the composited debris in a wide mouth plastic container and preserve with 80% ethanol (use a stronger concentration if there is a lot of debris in the sample). Include an internal tag with the station ID, date, sampler's initials and sample type inside the container with the debris (Figure 7). Attach an external sample tag to the outside of the container. Standard external tags for both biological and chemical samples are obtained from the state lab (Figure 8). Instead of an external tag, the site information can be written in indelible ink (i.e. Sharpie) on the sample lid. The external tag information must include the Station ID, Stream name, location, sampler's initials, date sampled, time sampled and sample type (Figure 10). A biological sample request form including, chain of custody, must be completed prior to delivery to the state lab for identification (Appendix B).

**c. Semi-Quantitative Bank Sample (SQBANK)**

In ecoregions 65a, 65b, 65e, 65i, 73a, 74b, collect a semi-quantitative bank sample (SQBANK) (even if riffles are present) for comparison to the reference criteria. Also, use the SQBANK method in 71i streams without riffle areas.

1. Use a triangular dip net with a 500-micron mesh to sample the rooted undercut bank. Collect the samples by jabbing the net below the surface of the water using an upward/forward thrusting motion designed to dislodge macroinvertebrates from the roots. Sample three separate areas of the reach including at least one sample from each bank if possible. Collect samples from different velocities and different bank types (i.e. overhanging tree roots, undercut grass banks) if possible. Macrophyte beds may be substituted if rooted banks are not available. Sample approximately one linear meter (approximately 3 triangular net widths) at each of the three sampling locations. It may be necessary to collect more than 3 sampling location to get 9 linear meters if habitat areas are small.
2. Thoroughly rinse the sample by gently swishing the net through the water. Do not let the net opening dip below the surface of the water. Visually inspect any large organic matter such as whole leaves and sticks. Remove any organisms clinging to these materials and add to the smaller debris, before discarding the large material. Using forceps, remove any organisms clinging to the net and add to the sample. Composite the debris from all three bank samples. If upon cursory examination of the debris, it does not appear that 200 organisms have been collected, additional bank samples may be collected. If all rooted bank habitat is exhausted before 200 organisms are collected, document on the stream survey field sheet. Document the total number and location of bank jabs on the stream survey field sheet and the number of bank jabs on the sample tag.
3. Place the composited debris in a wide mouth plastic container and preserve with 80% ethanol (a stronger concentration should be used if there is a lot of organic matter in the sample). Include an internal tag with the station ID, date, sampler's initials and sample type inside the container with the debris (Figure 7). Attach an external sample tag to the outside of the container. Standard external tags for both biological and chemical samples are obtained from the state lab (Figure 8). Instead of an external tag, the site information can be written in indelible ink (i.e. Sharpie) on the sample lid. The external tag information must include the Station ID, Stream name, location, sampler's initials, date sampled, time sampled and sample type (Figure 10). A biological sample request form, including chain of custody, must be completed prior to delivery to the state lab for identification (Appendix B).

## **Protocol H: Sample Logging and Lab Transport**

### **Any staff member**

Samples must be logged to allow complete reconstruction, from initial field records, through data storage and system retrieval. This includes biorecons that are identified in the field with no vouchers. Assign a discrete log number to each individual macroinvertebrate sample (including biorecons). For field offices, this will be an eight digit number determined in the following manner:

N0105001

Where:

The first digit (N) determines which office the sample is from:

|                      |                    |
|----------------------|--------------------|
| C = Chattanooga EFO  | K = Knoxville EFO  |
| L = Columbia EFO     | M = Memphis EFO    |
| V = Cookeville EFO   | N = Nashville EFO  |
| H = Johnson City EFO | S = Surface Mining |
| J = Jackson EFO      |                    |

The second and third digit represent the year sampled (01 = 2001)

The fourth and fifth digit represent the month sampled (05 = May)

The last three digits represent a consecutive number for the number of samples collected that month (001 = the first sample collected in May).

The field log numbers (along with the station ID) will be used to identify the sample on paperwork, tags, bench field sheets, logbooks, QC records, or any other place this sample is documented. Note for samples sent to the TDH lab for analysis, a second log number will be assigned by their LIMS system. Both the field number assigned by the collector and the LIMS number will follow the sample through analysis and be reported on data sheets.

A log is to be kept in the field office of all biological samples collected (Figure 13). It is recommended that this be an electronic log. A back-up copy in a separate location must be kept of all logs. The log entry must include the log number, station ID, date collected, time collected, collector's initials, sample source, station location, type of sample and date sent to the lab.

A second log will be kept at the lab which will also include sample identification information (Figure 14).

### Transport to Lab

All semi-quantitative samples collected by WPC environmental field offices are to be sent to the state laboratory (TDH) for identification as soon as possible after collection. (Samples collected by non-WPC staff may be identified by any qualified macroinvertebrate taxonomist who has met quality assurance requirements specified in Section II and follows the subsampling and taxonomic protocols specified in this document). The Nashville Lab is the only state laboratory with the capability to identify macroinvertebrate samples. The Knoxville and Jackson labs are certified to ship samples containing ethanol so samples may be delivered to any of the three labs. Ethanol is considered by OSHA to be a hazardous material, only certified personnel may ship samples. Any certified WPC staff can also ship samples directly from the EFO.

A biological sample request form, including chain of custody must be completed and accompany all biological samples (Appendix B). The Aquatic Biology Section no longer receives samples directly. All samples are to be delivered to the lab's sample coordinator for processing.

#### Sample priorities:

Biological sample priorities are set by the Planning and Standards Section who coordinates with the state lab. Before completing the "date needed" on the sample request form, contact PAS if results are needed outside the following priority.

- a. Watershed sample (including TMDLs and ecoregion sites) completed by December 31 of the fiscal year following the monitoring year for the group provided no sample is completed more than one year after receipt. For example Group 5 sample collection will start in July 2010 and end June 2011. Sample analysis is to be completed no later than December 2011. EFO QC samples will be completed the same time as the watershed group due date.
- b. Anti-degradation samples within 30 days of receipt.
- c. Special projects by agreed upon date as stipulated by grant.
- d. Priority samples – contact Aquatic Biology Section, if lab receives too many priority requests, PAS will coordinate.

| Log #    | Station ID   | Source   | Location          | Date Col. | Time Col. | Init. Col. | Type   | Date sent to lab |
|----------|--------------|----------|-------------------|-----------|-----------|------------|--------|------------------|
| K0203001 | DAVIS012.5CL | Davis Ck | 100 yds u/s Dairy | 3/6/02    | 1200      | JEB/DRM    | SQKICK | 9/10/10          |
| K0203002 | DAVIS001.3CL | Davis Ck | Hwy Z             | 3/6/02    | 1500      | JEB/DRM    | BR     | NA               |
|          |              |          |                   |           |           |            |        |                  |

**Figure 13: Macroinvertebrate Sample Collection Log**

| Lab Log #  | Field Log # | Station ID    | Source   | Location          | Date Col. | Time Col. | EFO | Init. Col. | Type   | Date Received by Lab | Sort By | Sort Date | ID By | ID Date | Date Reported |

**Figure 14: Macroinvertebrate Sample ID Log**

## **Protocol I - Subsampling Procedures for Semi-Quantitative Samples**

### **Biologist/Environmental Specialist with documented expertise in sorting.**

All semi-quantitative samples are to be reduced to a 200+/- 20% (160-240) organism subsample using the following technique. This method comes directly from section 7.3 (pages 7-9) of the 1999 guidance, Rapid Bioassessment Protocols for Use in Wadeable Streams and Rivers (EPA 841-B-99-002).

1. Thoroughly rinse the sample in a 500-micron mesh sieve to remove preservative and fine sediment. Large organic material (whole leaves, twigs, etc.) not removed in the field should be rinsed, visually inspected and discarded. It may be necessary to soak the sample contents in water for about 15 minutes to hydrate the benthic organisms, which will prevent them from floating on the water surface during sorting. If the sample was stored in more than one container, the contents of all containers for a given sample should be combined at this time. Gently mix the sample by hand while rinsing to make it homogenous.
2. Transfer the cleaned sample to a gridded pick subsampler (or similar apparatus). The subsampler is a white plastic cutting tray that measures approximately 18" x 12½" x 2¼". The tray is divided into 28, 2"x2" grids and marked with indelible ink. Note: it is preferable that a sieve insert or raised grid divider be used to separate the grids. Remove the animals and debris using a combination of scoop and transfer pipette.
3. If the debris will not fit in one tray, use two or more trays. Thoroughly mix the debris and divide equally between the trays. Sort the same grids for both trays. For example, if grid # 5 is randomly selected, both # 5 grids are picked. This will count as one grid out of 28.
4. Add enough water (or ethanol) to evenly distribute the debris. Gently shake and swirl the tray until the organisms are evenly distributed within the tray. Remove the excess water with a suction device (i.e. turkey baster with a 500 micron or smaller screen over the aperture), to the point where the sample is settled onto the bottom of the tray. If a raised grid insert is not being used, care should be taken not to pull organisms towards the area of suction.
5. Randomly select four numbers corresponding to squares (grids) within the gridded subsampling pan. Remove all material (organisms and debris) from the four grids and place the material into a dish or jar with a small amount of water. Use a magnifying light to make sure all organisms and debris were removed from the grids. Any organism that is lying over a line separating two grids is considered to be on the grid containing its head. If it is not possible to determine the location of the head (i.e. oligochaetes), the organism is considered to be in the grid containing most of the body.

6. If there appears to be 160-240 organisms (cumulative of the four grids) then subsampling is completed. If there appears to be fewer than 160 organisms, continue selecting grids one at a time until between 160 and 240 organisms are selected. If more than 240 organisms are contained in the first four grids, transfer the contents of the four grids to a second gridded pan. Randomly select grids for this second subsampling as was done for the first, sorting grids four (and then one) at a time until the second subsample contains 160-240 organisms. If it is estimated that the first four grids of the second subsample contain more than 240 organisms, transfer the four grids to another pan and conduct a third subsample. Continue creating subsamples until there are 160-240 organisms.
7. Transfer the subsample, a small amount at a time to a petri dish for sorting (removing organisms). Complete all sorting under a dissecting scope, removing and preserving all organisms in 80% ethanol. If the number of organisms from the four-grid subsample does not equal the specified number of 160-240, randomly choose a fifth grid and pick out all organisms in that grid. If the addition of the fifth grid fulfills the quota, than the subsampling is complete. If not, choose additional grids (one at a time) until the quota is reached or surpassed. All the organisms from the final grid that is randomly selected are removed even if the quota is reached midway through the picking of the grid.

If, after microscopic sorting, more than 240 organisms are found, transfer all organisms to a small gridded dish (36 grids). Subsample by groups of first four and then one random grid until the target of 160-240 organisms is achieved.

8. Place the sorted debris in a separate container and preserve in 80% ethanol. Include both external and internal tags (Figures 2 and 3). Add the words "sorted debris" to the tag information. Save the remaining unsorted sample debris residue in a separate container labeled "sample residue". This container should include the original sample label and internal tag.
9. Place the sorted 160-240 organism subsample into a glass vial and preserve in 80% ethanol. Place an internal tag written in pencil on waterproof paper citing the log number, station ID, date collected and taxonomist inside each vial (Figure 4). Position the label so it can be read through the vial.

All chironomids and oligochaetes in the subsample are to be identified individually (do not subsample and extrapolate). Mount slides in a permanent mounting media (i.e. CMCP-10). Label slides with the station id, date collected, taxonomist initials and slide box number.

10. After sorting is completed, record the appropriate information (log number, station ID, sorters initials, date sorted and the number of organisms found) in the QC logbook (Figure 8, Section II-C).
11. All organisms and debris shall be retained as separately preserved samples for at least 5 years.

**Protocol J - Taxonomy of Semi-Quantitative Samples**

**Biologist/Environmental Specialist with documented expertise in macroinvertebrate taxonomy**

Semi-quantitative samples are to be sent to the central lab for analysis. This is to be coordinated through the Planning and Standards Section.

1. Identify all organisms to genus except Acari, Nematoda, Hydra, Brachiobdellida, immature Tubificidae, Lumbriculidae and Nematomorpha using the primary taxonomic keys listed in Appendix D. Do (Secondary keys will only be used to assist with difficult specimens.) Do not count animals that are missing heads, exuviae, empty shells, empty caddis cases, or terrestrial life stages.
2. Calculate all biometrics at the specified level only. The primary keys will be updated as new literature is available. It is important that all taxonomists use the same primary keys for consistency in identification and nomenclature.
3. Record taxonomic nomenclature and number of organisms on a bench sheet. Header information that must be provided includes the log number, station ID number, date collected, time collected, samplers, sample source location, ecoregion, sample type, taxonomist and analysis date. Taxonomic information should include order, family and genus. An example is provided in Figure 15 (format can vary as long as all the information is provided).

| <b>STATION ID:</b> HOHUM012.3SE    |                 | <b>LOG NUMBER:</b> C0203007                  |              |

| Ephemeroptera                      | Heptageniidae   | Epeorus                                      | 20           |
| Ephemeroptera                      | Heptageniidae   | Stenacron                                    | 30           |
| Ephemeroptera                      | Leptophlebiidae | Paraleptophlebia                             | 2            |
| Plecoptera                         | Leuctridae      | Leuctra                                      | 9            |
| Trichoptera                        | Hydropsychidae  | Cheumatopsyche                               | 32           |

**Figure 15: Example of taxonomic bench sheet**

4. After identifying all taxa in the subsample, return them to the vial and add fresh preservative (80% ethanol). Initial, date and add the log number to the internal tag (Figure 10). Store the sample for a minimum of five years.

5. Mount chironomids, oligochaetes and other small organisms on slides for identification. Use a permanent mounting media such as CMCP-10 which clears the mount so a separate clearing agent is not necessary. Use round coverslips (12 mm) for small specimens. Place one organism under each coverslip. A maximum of 10 coverslips can be placed on each slide. Square coverslips (22mm) can be used to mount larger specimens. Place one to three organisms under each coverslip with a maximum of 3 coverslips per slide.

Mount chironomid larvae so that their bodies are viewed laterally and their heads are viewed ventrally. Apply enough pressure to the coverslip so that the mandibles are opened exposing the mentum. The S1 setae, premandibles and pectin epipharyngias should also be visible. Mount oligochaetes laterally with minimal pressure. The mounting media should extend past the edges of the coverslip to allow for shrinkage during drying. Allow the slides to air-dry at least 24 hours before attempting identification. (A slide dryer can be used to dry mounts faster if desired). Label slides with the log number, station ID, date, taxonomist initials and slide box slot number. Keep labeled slides in a slide box a minimum of five years after completion of the study.

Note: Do not subsample chironomids and oligochaetes further. Identify each chironomid and oligochaete in the 160-240 organism subsample.

## Protocol K - Data Reduction of Semi-Quantitative Samples

### Biologist/Environmental Specialist with experience in macroinvertebrate taxonomy

A macroinvertebrate index, based on seven biometrics, has been developed by the Division for use in semi-quantitative macroinvertebrate surveys (Arnwine and Denton, 2001). This index is based on ecoregional reference data and calibrated by bioregion. The calibrated scoring criteria can be used in all streams that fit the sample criteria for that region (habitat sampled, sampling protocol, stream size) and have at least 80% of their upstream drainage in the same bioregion.

For streams that do not meet the profile (for instance non-riffle streams in bioregions that are calibrated to a SQKICK sample, streams that have more than 20% of their upstream drainage in other bioregions or streams whose drainage area is larger or small than that specified in biocriteria), calculate the same seven biometrics. However, the index tables cannot be used for assessment, since these samples are not comparable to streams in the ecoregion reference database. Compare the biometrics to an appropriate upstream or watershed reference.

1. Using the raw benthic data from the semi-quantitative subsample (kick or bank), calculate a numerical value for each of the seven biometrics. Calculate all biometrics using taxa identified to the genus level except for specified taxa (Acari, Branchiobdellida, Nematomorpha, Nematoda, Hydra, immature Tubificidae, Lumbriculidae) or those too young or too damaged to identify to this level. Species identification is not to be used.

- a. **TR** (Taxa Richness)

Total the number of distinct genera found in the subsample. Taxa that could only be identified to family are included only if it is probable that they are distinct from other taxa identified to genus within the family. (Document on taxa list if an unidentified organism is determined to be a distinct taxon.)

- b. **EPT** (Ephemeroptera Plecoptera Trichoptera Richness)

Total the number of genera within the orders Ephemeroptera, Plecoptera and Trichoptera. Taxa that could only be identified to family are included only if they are the only taxon found in that family or it is probable that they are distinct from other taxa identified to genus within the family. (Document on taxa list if an unidentified organism is determined to be a distinct taxon.)

- c. **% EPT-Cheum** (EPT Abundance excluding *Cheumatopsyche* spp.)

$$\% \text{ EPT} = \frac{\text{Total (Ephemeroptera + Plecoptera + Trichoptera)} - \text{Cheumatopsyche}}{\text{Total number of individuals in the subsample}} \times 100$$

d. **%OC** (Percent oligochaetes and chironomids)

$$\%OC = \frac{\text{Total number of Oligochaeta} + \text{Chironomidae}}{\text{Total number of individuals in the subsample}} \times 100$$

e. **NCBI** (North Carolina Biotic Index includes tolerance scores from other indices found in EPA RBP when no value is available for NC). Family value is to be assigned when there is no genus level tolerance value.

$$NCBI = \frac{\sum x_i t_i}{N \text{ (exclusive if no } t_i)}$$

where:  $x_i$  = number of individuals within a taxon

$t_i$  = tolerance value of a taxon (Appendix C)

N = total number of individuals in the subsample that have been assigned a tolerance value (exclude animals for which no tolerance value is assigned see following note).

Note: For new taxa, tolerance values found in the latest version of the North Carolina Department of Environment and Natural Resources QSSOP should be assigned <http://h2o.enr.state.nc.us/esb/BAUwww/benthossop.pdf>. If only species level tolerance values are available, genus level is determined by averaging species. If a North Carolina tolerance score has not been assigned for a taxon, regional tolerance values in appendix B of EPA's Rapid Bioassessment protocols may be substituted. (Barbour et. al., 1999). Order of preference is Southeast, Midwest, Upper Midwest, Mid-Atlantic then Northwest. If there is no genus level tolerance value for new taxon in any of these documents, the family level tolerance value found in appendix C should be used.

f. **% Clingers** (Percent contribution of organisms (primary for genus) that build fixed retreats or have adaptations to attach to surfaces in flowing water)

A list of taxa designated as clingers is located in Appendix C. Merritt and Cummins, 2008 is used as authority for determination of primary clingers (if multiple habits are listed, only those where clinger is listed first are used.)

$$\% \text{ Clingers} = \frac{\text{Total number of clinger individuals}}{\text{Total individuals in the sample}} \times 100$$

g **%TNUTOL (% TN Nutrient Tolerant Organisms)**

% TNUTOL = Total number of Cheumatopsyche, Stenelmis,  
Polypedilum, Cricotopus, Cricotopus/Orthocladius,  
Lirceus, Caenis, Elimia, Nais, Dero, Undetermined  
(immature) Tubificidae

X 100

---

Total individuals in the sample

After calculating values for the seven biometrics, equalize the data by assigning a score of 0, 2, 4 or 6 based on comparison to the ecoregion reference database for the bioregion and stream size (Appendix A). Total the seven scores to calculate the TMI (Tennessee Macroinvertebrate Index). **A score of 32 or higher is considered to pass biocriteria guidelines in all ecoregions except 73 where a score of 22 is passing (EPT Richness and % Clingers is not calculated in ecoregion 73).**

Alternative Reference Stream Method

Some sites may not meet the conditions necessary for comparison to the biocriteria tables in Appendix A. This will happen when:

- a. The streams has less than 2 square miles drainage upstream of the sample site and headwater guidelines have not yet been developed for that bioregion. Drainage area size can be determined at <http://water.usgs.gov/osw/streamstats/tennessee.html>.
- b. The stream is less than 80% within a bioregion upstream of the sample site.
- c. The stream does not naturally have the habitat specified for comparison (for example low gradient non-riffle streams in bioregions where riffle criteria are specified. However, streams where the riffle is buried in sediment or otherwise compromised due to human disturbance should still be considered riffle streams).

In these cases, an alternative reference sample should be collected. The reference can be upstream, within the same watershed or within the same bioregion. Reference site selection should follow the same guidelines used for selection of ecoregion reference streams as specified in Protocol M. The alternative reference should be collected at the same time and using the same method (SQKICK or SQBANK) used at the test site.

Once the reference sample is collected, scoring ranges for each metric will be calculated based on quadrisection of the reference values for each metric. Reference data and scoring table, including ranges calculated for each metric, should be included with data report.

For metrics that were expected to decrease with increased pollution (TR, EPT, %EPT-Cheum, %Clingers):

Score 6:  $\geq$  reference value – Reference value/4

Score 4:  $<$  lowest possible 6 to lowest possible 6 – reference/4

Score 2:  $<$  lowest possible 4 to lowest possible 4 – reference/4

Score 0:  $<$  lowest possible 2

For example:

If there were 30 distinct taxa found at the reference site, the scoring for taxa richness would be calculated by

Score 6:  $30 - (30/4)$  or  $\geq 22$

Score 4:  $22 - (30/4)$  or 14 to 21

Score 2:  $14 - (30/4)$  or 6 to 14

Score 0:  $< 6$

For metrics that were expected to increase with increased pollution (%OC, NCBI, %TNUTOL):

Score 6:  $<$  reference value + (highest possible value for metric – reference value)/4

Score 4:  $>$  highest possible 6 to highest possible 6 + (highest possible value for metric – reference value)/4

Score 2:  $>$  highest possible 4 to 0.1 + highest possible 4 + (highest possible value for metric – reference value)/4

Score 0:  $>$  highest possible 2

For example, if the %OC at the reference site was 20%,

Score 6:  $\leq 20\% + [(100\% - 20\%)/4]$  or  $\leq 40.0\%$

Score 4:  $40\% + (100\% - 20\%)/4$  or 40.1% to 60.0%

Score 2:  $60\% + (100\% - 20\%)/4$  or 60.1% to 80.0%

Score 0:  $> 80.0\%$

Total the 7 scores to calculate the TMI. A score of 32 or higher is considered to pass biocriteria guidelines in all ecoregions except 73 where a score of 22 is passing (EPT Richness and % Clingers is not calculated in ecoregion 73).

## **Protocol L: Report Preparation**

### Biorecons

Biorecon results including biorecon field sheet, with final identifications and scores, habitat assessment field sheets, stream survey field sheets should be sent to the Planning and Standard section as soon after completion of assessment as possible. Data packets may be submitted hard copy or electronically with each survey in a separate file. Photos should be sent electronically at the end of the fiscal year, prior to assessments. File names should incorporate station ID and date.

### Semi-quantitative Samples

a. Field office

As soon after collection as possible, submit all samples and paperwork (sample request form/COC, habitat assessments, stream survey field sheet) to the state laboratory sample coordinator. Field office should maintain copy of all paperwork and voucher specimens for a minimum of five years.

b. Aquatic Biology Section – State Laboratory

After sample completion and QC (by agreed due date) send copies of macroinvertebrate assessment field sheet, taxonomic lists, stream survey field sheet, habitat assessment field sheet, sample request form/COC, and any other paperwork such as printed pictures that were submitted with the sample to the Planning and Standards Section and appropriate field office. Electronic submittal is acceptable.

Results should not be submitted until QC is complete. However, data should not be held past due date. Instead, QC should be completed prior to completion of group of 10. If the last sample QC'd fails, the next group of 10 should start after the failed sample. If the sample passes, additional QC does not need to be done until 10 samples are completed for that group.

Taxonomic data should be entered in the SQSH database for metric calculation and electronic storage. The database should be sent to the Planning and Standard Section quarterly.

### Photographs

Each field office should provide the Planning and Standards Section with a CD/DVD containing pictures of sample locations at the end of each fiscal year prior to assessments. File names should incorporate station ID and date.

### **Protocol M: Reference stream selection**

The following guidelines are for selection of ecoregion reference streams. When selecting a project specific reference sites for atypical test streams the same guidelines should apply. Stream size, habitat, gradient and geology should be similar to the test site.

- Stream type, flow regime and substrate are typical of the Level IV ecoregion (or test site for atypical streams). Perennial streams will be targeted. Intermittent streams may be selected if this is typical of headwaters for the ecoregion.
- Streams are in a protected watershed or upstream land-use is primarily forested. In heavily urban or agricultural bioregions, stations will be selected where upstream watershed is least disturbed and is comparable to percent forested of other established reference streams.
- Riparian vegetation zone is well established with all size classes represented. Invasives constitute less than 10% of streamside vegetation.
- The upstream watershed does not contain a municipality, mining area or permitted discharger and is not heavily impacted by nonpoint source or other non-regulated source of pollution.
- Upstream drainage is at least 80% within a single Level IV ecoregion.
- The stream flows in its natural channel. There are no flow or water level modification structures such as dams, irrigation canals or field drains.
- No power lines or pipelines or any structure that is routinely cleared crosses upstream of the monitoring station.
- The upstream watershed contains few or no roads.

## **I.J - DATA AND RECORDS MANAGEMENT**

Biorecon and semi-quantitative stations are established in the same Water Quality Database as chemical monitoring stations. The master database is kept on the H drive at the central office. The Planning and Standards Section is responsible for maintaining this database. The database is sent to the environmental field offices at the beginning of each quarter. The file name is Copy of wqlkcCO-EFO (current date). The Quality Team member or their designee in each EFO should check that all biological stations for their area have been entered with complete information and that duplicate sites do not exist under another station ID. Biorecon results are entered in the biorecon form of this database. Biological and chemical stations collected within 200 meters (yards) of each other are considered the same station and should be given the same station ID. (See station naming protocol for more information). After reviewing the stations table, an excel spreadsheet showing corrections should be sent to the Planning and Standards Section.

Taxa lists from semi-quantitative samples are entered by the Aquatic Biology Section, Lab Services, TDH in a 2000 Access file called SQDATA (date). Copies of taxa lists and habitat field sheets from any semi-quantitative samples identified by WPC Environmental Assistance Centers are to be sent to the Aquatic Biology Section for data entry. This database will be sent by the Aquatic Biology Section to the Planning and Standards Section at the completion of each project or quarterly as required. Calculated metrics for each sample will be entered by the PAS section in Water Quality Database.

Assessment information for each stream segment will be entered in the Assessment Database (ADB) by the Planning and Standards Section (PAS). PAS staff will meet with WPC managers and biologists in each EFO before assessments are finalized. This database is linked to a GIS map and is accessible on the web for public access: <http://tnmap.tn.gov/wpc/>

The original field sheets and taxa lists are kept in files at the sampling agency (Environmental Field Office or Aquatic Biology Section). Copies of all paperwork should accompany samples sent to the Aquatic Biology Section for analysis. The Aquatic Biology section will send copies of taxa lists, field and habitat forms, COC, and the macroinvertebrate assessment report to the PAS section and the appropriate field office. The Aquatic Biology Section will also send copies of all paperwork to the appropriate Environmental Field Office for projects where they collect the samples. For biorecons or other samples identified by the field offices, copies of the Stream Survey Field Sheet, Habitat Assessment Field Sheet and taxa lists along with Macroinvertebrate Assessment Report (Appendix B) are to be sent to the Planning and Standards Section. These copies will be kept in the watershed files for five years before being transferred to archive boxes. The Aquatic Biology Section will also keep copies of all paperwork and samples for five years after report date.

## II. QUALITY ASSURANCE /QUALITY CONTROL

The U.S. EPA requires that a centrally planned, directed and coordinated quality assurance and quality control program be applied to efforts supported by them through grants, contracts or other formalized agreements. This time allocation is an essential component of biological sampling and analysis and will be included in annual work plans. This is not an optional or “as time allows” activity. The goal is to demonstrate the accuracy and precision of the biologists, as well as the reproducibility of the methodology, and to ensure unbiased treatment of all samples.

### A. General QC Practices

1. Quality Team Leader (QC Coordinator) - A centralized biological QC coordinator will be designated with the responsibility to ensure that all QC protocols are met. This person will be an experienced water quality biologist in the Planning and Standards Section. Major responsibilities will include monitoring QC activities to determine conformance, distributing quality related information, training personnel on QC requirements and procedures, reviewing QA/QC plans for completeness, noting inconsistencies, and signing off on the QA plan and reports.
2. Quality Team Member (In-house QC officer) - One WPC biologist/environmental specialist in each EFO will be designated as the Quality Team Member (in-house QC officer.) This person will be responsible for performing and/or ensuring that quality control is maintained and for coordinating activities with the central Quality Team Leader (QC coordinator).
3. Training - Unless prohibited by budgetary travel restrictions, training will be conducted at least once a year through workshops, seminars and/or field demonstrations in an effort to maintain consistency, repeatability and precision between biologists/environmental specialists conducting macroinvertebrate surveys. This will also be an opportunity for personnel to discuss problems they have encountered with the methodologies and to suggest SOP revisions prior to the annual SOP review. Note: topics of discussion should be submitted to the central Quality Team Leader (QC coordinator) before the meeting so that a planned agenda can be followed, thus making the best use of limited time.

### B. Field Quality Control – Habitat Assessment and Biological Sampling Methodology

1. Habitat Assessments - At minimally 10% of sites, two trained biologists/environmental specialists will complete habitat assessment field sheets independently. Scores are compared for each parameter with discrepancies arbitrated while in the field. A separate consensus field sheet should be submitted with both original data sheets. Circle on stream survey field sheet if duplicate and/or consensus completed.
2. Biorecon Collection A second biorecon will be collected at a minimum of 10% of the sites by a separate biologist/environmental specialist. This should be conducted at the same time,

or at least within two weeks of the original survey. If assessment does not agree (not-impaired, ambiguous, or impaired) biologists should investigate reason for disagreement. Results from the more representative sample should be used. If no reason could be determined for discrepancy, both biologists should collect another sample.

3. Semi-quantitative Sample - A second semi-quantitative sample will be collected at 10% of the sites within 2 weeks of the original sample. (If rain or other factor compromises reproducibility, the second sample should not be collected). Since this sampling method requires two people, it will not be possible in most offices for an independent team to conduct the sampling. Therefore, the same team can collect the samples with each investigator independently selecting the sample spot and performing the kick. At least once a year, a team from another EFO or the state lab should collect the QC sample.

If assessment results do not agree (both scores above or below 32) the following action will take place until agreement is reached:

- a. The samplers will be contacted to determine if there was any discrepancy in habitat, location, environmental factors such as rain or collection methods. If so, the most representative sample will be used. This will not count as part of the required 10% duplicates.
  - b. The lab will re-id both samples
  - c. The lab will re-examine both subsamples for overlooked organisms and re-id
  - d. The lab will re-subsample and id both samples
  - e. Both taxa lists will be submitted to PAS. Taxa will be combined, statistically reduced to a 200 organisms subsample and re-scored. This will not count as a QC sample.
4. Chain of Custody Chain of custody is required by the TDEC Office of General Counsel for samples that have the potential of being used in court, reviewed by state boards, or involved in state hearings. Chain of custody must also accompany any contract samples (semi-quantitative samples being sent to the lab). Chain of custody is the far right column of the biological analysis form. (Appendix B) The entire form must be filled out completely.

The chain of custody follows the sample through collection, transfer, storage, taxonomic identification, quality assurance and disposal. The biologist who collected the sample must sign (not print) their name in full (not initial) in the Collected By space with the date and time (24-hour clock). If the sample is given to anyone else before it is delivered to the lab, each person responsible for the sample must sign their full name on the Received By space with the date and time. The person in the laboratory who receives the sample will sign line four. The person who logs the sample in signs the last line.

### **C. QC Log**

A list of all samples sorted and/or identified by each biologist/environmental specialist will be kept in a bound log (or electronically with electronic backup on a separate system) so that QC requirements and results can be documented (Figure 16). The QC log must contain the following information:

1. Sample log number
2. Station ID
3. Sample type
4. Initials of taxonomist and sorter
5. Number of organisms picked in subsample (semi-quantitative samples only)
6. Date completed
7. Initials of person performing QC
8. Number of organisms found in re-pick (semi-quantitative samples only)
9. Percent sorting efficiency (semi-quantitative samples only).
10. Date of QC identification
11. Initials of QC taxonomist
12. Results of taxonomic QC (satisfactory/unsatisfactory)

| Log #    | Station ID   | Sample Type | Sort By | Sort Date | # org. | Sort QC | QC Date | QC # org. | Sort Eff. | S/U | ID By | ID Date | QC ID | QC Date | S/U |
|----------|--------------|-------------|---------|-----------|--------|---------|---------|-----------|-----------|-----|-------|---------|-------|---------|-----|
| J0201001 | BIFFL003.0DY | SQKICK      |         |           |        |         |         |           |           |     |       |         |       |         |     |

Figure 16: Example of macroinvertebrate QC log

**D. Sorting Efficiency (Semi-Quantitative samples only)**

1. Each biologist/ES responsible for sample sorting, regardless of previous experience, will have every sample QC'ed by a second biologist/ES who has already achieved 90% sorting efficiency (documented) until the original biologist/ES has passed 90% sorting efficiency on a sample. A record of this is kept in the QC log. Once a biologist/ES has passed their first QC, they are QC'ed on 10% of subsequent samples (randomly selected).
2. Each biologist/ES involved in sorting of semi-quantitative benthic macroinvertebrate samples will have 10% of their subsamples (debris) resorted by a second experienced biologist/ES. The sample to be QC'ed is randomly chosen by the person performing the QC after every group of 10 samples has been completed. (Or fewer if less than 10 are completed before due date). A sorting efficiency of 90% must be maintained. If fewer than 90% of the organisms are recovered, every sample prior to that one in the same group of 10 is resorted until a sample that has met the 90% requirement is found. The next group of 10 starts after the unsatisfactory sample.

The sorting efficiency is calculated by:

$$\text{Sorting efficiency} = \frac{\# \text{ organisms found in initial pick}}{\text{Total \# organisms, both picks}} \times 100$$

If fewer than 90% of organisms are found, the additional animals are added to the final ID of the first pick. If this puts the final subsample over 240 organisms transfer all organisms to a small gridded dish (36 grids). Subsample by groups of first four and then one random grid until the target of 160-240 organisms is achieved. If permanent mounts have already been made of the first pick, a 200 organism subsample should be calculated statistically:

$$\text{Taxon a} = 200 * \frac{\# \text{ taxon a found in both picks}}{\text{Total \# organisms both picks}}$$

Round to nearest whole number.

3. Log results in the QC log.
4. All sorting QC must be completed before the data are released to ensure accuracy of results. However samples, should not be held up waiting for QC. Instead QC should be performed prior to completion of group of 10. If, for any reason, a report is released prior to QC completion, an addendum will be sent to all report recipients with any corrected information after QC is complete.
5. All subsample debris is preserved in 80% ethanol and kept in a labeled container for a minimum of 5 years. The original sample, from which the subsample was taken, is kept in a separate labeled container for the same period.

## **E. Taxonomic Verification**

1. All biologists/ES are to be trained and show proficiency for genus level identification of each group of organisms. (Except Acari, Nematoda, Nematomorpha, Branchiobdellida, Enchytraeidae and Lumbriculidae). If the biologist/ES will only be performing family level biorecons, they need only demonstrate proficiency at the family level.
2. The same taxonomic keys for each group will be used by all taxonomists. Consistency in taxonomic keys is essential because couplets in different keys can result in identification discrepancies through differences in nomenclature or inconsistency of characters used for separation of taxa. This is particularly true where genera may exhibit great variability due to regionalization. Approved keys are listed in Appendix D. Keys will be updated continually as new literature is made available. However, biologists/ES should not utilize new keys for anything other than supplemental information until they are approved by the central QC coordinator and incorporated into the SOP to be used by all Division biologists/ES. New literature will be discussed at the annual training meetings. If new keys are approved for use as primary keys, taxa from reference stations will be reviewed to ensure that the most recent nomenclature is being used for reference information.
3. Each new biologist/ES, regardless of previous experience, will have every sample QC'ed by another biologist/ES (who has passed QC) until they have satisfactorily completed taxonomic QC on a sample. A record of this is kept in the QC log. Once a biologist/ES has satisfactorily completed their first QC, 10% of their identified samples will be randomly checked by another biologist/ES. The sample to be QC'ed is randomly chosen by the QC'er after every 10<sup>th</sup> sample is completed (or fewer depending on due date). The biologist/ES performing the QC will identify every organism in the sample without consulting the original taxonomist's list. Once the second identification is complete, the two biologists/ES will go over any discrepancies together.
4. To satisfy QC requirements for Semi-Quantitative samples, the two taxa lists must not show a significant difference as measured by a chi-square test utilizing a contingency table at alpha 0.05. If a sample shows a significant difference, every sample prior to that one in the same group of 10 will be checked until a sample that has met the QC requirement has been found. The next group of 10 will start after the unsatisfactory sample. For biorecons, assessment results must be the same (supporting, ambiguous or non-supporting) to pass QC. (Note for family level biorecons where complete vouchers are not collected on every sample, taxonomic QC will be on every 10<sup>th</sup> sample instead of random).

Note: If both taxonomic QC is performed on the same sample where sorting efficiency is checked, only the animals found in the original pick will be used for QC.

5. Log results in the QC logbook.

6. Complete all taxonomic QC before releasing results ensure accuracy of results. Reports should never be held waiting for QC, if necessary perform QC prior to completion of group of 10. If, for any reason, results are released prior to QC completion, send an addendum to all report recipients with any adjusted information after QC is complete.

## **F. Voucher Collections**

1. Family Level Biorecons – Representative specimens of families difficult to field identify, should always be collected for dissecting scope verification. Voucher collections including representatives of each taxon must be collected at a minimum of 10% of sites (randomly selected) for verification by dissecting scope. If mis-identifications occur, vouchers should be collected at all sites for those families missed until biologist has demonstrated proficiency in field identifications for that taxon.
2. Genus level – Vouchers collections including representatives of each taxon must be collected at every site for verification by dissecting scope.
3. All voucher samples must be maintained for five years.

## **G. Reference Collections**

1. The designated QC officer (quality team member) for each EFO will maintain a permanent reference collection consisting of all taxa identified by that office. In addition, a master collection of all taxa identified in the state will be kept in the central laboratory. The organisms in the centralized master reference collection will be verified by outside experts recognized for expertise in a particular taxonomic group.
2. A list of verified organisms found in the state is provided in Appendix E. If new organisms, not on the verified state taxa list are identified by the EFO, the quality team member will send a representative of that taxon to the central laboratory. The laboratory will have the new taxon verified by an outside expert, will add the organism to the central reference collection and will notify all regional offices and PAS of its addition to the verified taxa list for Tennessee. Experts used for verification must meet the qualifications provided in Appendix E.
3. Each EFO and central laboratory reference collection will be catalogued with discrete collection numbers assigned to each taxon in each facility. Assign unique numbers that identify the reference location to specimens as they are added into the collection. For example, if sequential numbering is used, N0001 would be the first specimen in the Nashville EFO collection. Maintain an accession catalog of all reference material in a permanently bound log or electronic format with backup on a separate system. Each entry must contain the following information:

Accession number (This must be unique for each group of organisms in each collection)  
Complete name (genus, authority = who id'd or verified it, date identified)  
Higher taxa (family, order, class)  
Locality data (Waterbody, location, county, ecoregion, station id)  
Sample habitat  
Name of collector/date of collection  
Name of taxonomist  
Name of verifier if appropriate  
Number of specimens

4. Arrange specimens for ease of use, (according to accession number or in phylogenetic order). Retain wet specimens in 80% ethanol in small screw cap vials with rubber or Teflon lined caps or rubber stoppered vials. Retain large specimens in appropriate size specimen jars sealed with electrical tape to reduce evaporation. Inspect vials monthly for evaporation adding 80% ethanol as needed. Keep permanently mounted microscope slides in a slide storage box. Seal the edges of the coverslips to prevent shrinkage of media over time (clear nail polish works well).
5. Clearly label all reference vials and slides. Place the labels in the vial with wet specimens or attach to slides for mounted specimens. Label information at a minimum must include:

Full name of the organism (Order, family, genus)  
Accession number (reference number)  
Station ID number  
Ecoregion  
Collection date  
Collector  
Taxonomist  
Verifier.

## **H. Data Reduction QC**

1. Store raw data (non-manipulated) in one or more separate locations and in an electronic database with backup.
2. A second staff member checks all computer data entry correctness by direct comparison with the field or laboratory handwritten data sheets. The person performing the data entry QC initial and dates each page of the checked printout in red ink
3. A second staff member checks ten percent of all biometrics that were hand calculated. If an error is found, all of the calculations for that biometric in that sample set are checked. The person performing the QC initials and dates each checked metric in red ink.

4. Keep QC information in a file with the other information for that project a minimum of five years.
5. Complete all data reduction QC before results are released.

|  | <b>Optimal</b>   |    |    |    |                      | <b>Suboptimal</b>  |    |    |    |                         | <b>Marginal</b>   |   |   |   |   | <b>Poor</b>  |   |   |   |   |
| <b>1. Epifaunal Substrate/ Available Cover</b> | Over 70% of stream reach has natural stable habitat suitable for colonization by fish and/or macroinvertebrates. Four or more productive habitats are present.                     |    |    |    |                      | Natural stable habitat covers 40-70% of stream reach. Three or more productive habitats present. (If near 70% and more than 3 go to optimal.)  |    |    |    |                         | Natural stable habitat covers 20 -40% of stream reach or only 1-2 productive habitats present. (If near 40% and more than 2 go to suboptimal.)      |   |   |   |   | Less than 20% stable habitat; lack of habitat is obvious; substrate unstable or lacking.   |   |   |   |   |
| SCORE  | 20   | 19 | 18 | 17 | 16                   | 15   | 14 | 13 | 12 | 11                      | 10  | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |  |    |    |    |                      |  |    |    |    |                         |   |   |   |   |   |  |   |   |   |   |
| <b>2.Embeddedness of Riffles</b>               | Gravel, cobble, and boulders 0-25% surrounded by fine sediment. Layering of cobble provides diversity of niche space. If near 25% drop to suboptimal if riffle not layered cobble. |    |    |    |                      | Gravel, cobble and boulders 25-50% surrounded by fine sediment. Niches in bottom layers of cobble compromised. If near 50% & riffles not layered cobble drop to marginal.                |    |    |    |                         | Gravel, cobble, and boulders are 50-75% surrounded by fine sediment. Niche space in middle layers of cobble is starting to fill with fine sediment. |   |   |   |   | Gravel, cobble, and boulders are more than 75% surrounded by fine sediment. Niche space is reduced to a single layer or is absent.                                       |   |   |   |   |
| SCORE  | 20   | 19 | 18 | 17 | 16                   | 15   | 14 | 13 | 12 | 11                      | 10  | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |  |    |    |    |                      |  |    |    |    |                         |   |   |   |   |   |  |   |   |   |   |
| <b>3. Velocity/ Depth Regime</b>               | All four velocity/depth regimes present (slow-deep, slow-shallow, fast-deep, fast-shallow).  |    |    |    |                      | Only 3 of the 4 regimes present (if fast-shallow is missing score lower). If slow-deep missing score 15.   |    |    |    |                         | Only 2 of the 4 habitat regimes present (if fast-shallow or slow-shallow are missing, score low).   |   |   |   |   | Dominated by 1 velocity/depth regime. Others regimes too small or infrequent to support aquatic populations.   |   |   |   |   |
| SCORE  | 20   | 19 | 18 | 17 | 16                   | 15   | 14 | 13 | 12 | 11                      | 10  | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |  |    |    |    |                      |  |    |    |    |                         |   |   |   |   |   |  |   |   |   |   |
| <b>4. Sediment Deposition</b>                  | Sediment deposition affects less than 5% of stream bottom in quiet areas. New deposition on islands and point bars is absent or minimal.   |    |    |    |                      | Sediment deposition affects 5-30% of stream bottom. Slight deposition in pool or slow areas. Some new deposition on islands and point bars. Move to marginal if build-up approaches 30%. |    |    |    |                         | Sediment deposition affects 30-50% of stream bottom. Sediment deposits at obstruction, constrictions and bends. Moderate pool deposition.           |   |   |   |   | Heavy deposits of fine material, increased bar development; more than 50% of the bottom changing frequently; pools almost absent due to substantial sediment deposition. |   |   |   |   |
| SCORE  | 20   | 19 | 18 | 17 | 16                   | 15   | 14 | 13 | 12 | 11                      | 10  | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |  |    |    |    |                      |  |    |    |    |                         |   |   |   |   |   |  |   |   |   |   |
| <b>5. Channel Flow Status.</b>                 | Water reaches base of both lower banks and streambed is covered by water throughout reach. Minimal productive habitat is exposed.  |    |    |    |                      | Water covers > 75% of streambed or 25% of productive habitat is exposed.   |    |    |    |                         | Water covers 25-75% of streambed and/or productive habitat is mostly exposed.   |   |   |   |   | Very little water in channel and mostly present as standing pools. Little or no productive habitat due to lack of water.   |   |   |   |   |
| SCORE  | 20   | 19 | 18 | 17 | 16                   | 15   | 14 | 13 | 12 | 11                      | 10  | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2 | 1 |

|---|---|---|--|---|--|----------------|--|--|--|--|
|   | <b>Optimal</b>  | <b>Suboptimal</b>   | <b>Marginal</b>  | <b>Poor</b>   |  |                |  |  |  |  |
| <b>6. Channel Alteration</b>  | Channelization, dredging rock removal or 4-wheel activity (past or present) absent or minimal; natural meander pattern. NO artificial structures in reach. Upstream or downstream structures do not affect reach. | Channelization, dredging or 4-wheel activity up to 40%. Channel has stabilized. If larger reach, channelization is historic and stable. Artificial structures in or out of reach do not affect natural flow patterns. | Channelization, dredging or 4-wheel activity 40-80% (or less that has not stabilized.) Artificial structures in or out of reach may have slight affect.    | Over 80% of reach channelized, dredged or affected by 4-wheelers. Instream habitat greatly altered or removed. Artificial structures have greatly affected flow pattern.                    |  |                |  |  |  |  |

| <b>7. Frequency of re-oxygenation zones.</b> Use frequency of riffle or bends for category. Rank by quality.  | Occurrence of re-oxygenation zones relatively frequent; ratio of distance between areas divided by average stream width <7:1.   | Occurrence of re-oxygenation zones infrequent; distance between areas divided by average stream width is 7 - 15.  | Occasional re-oxygenation area. The distance between areas divided by average stream width is over 15 and up to 25.  | Generally all flat water or flat bedrock; little opportunity for re-oxygenation. Distance between areas divided by average stream width >25.  |  |                |  |  |  |  |

| <b>3. Pool Variability</b>                     | Even mix of large-shallow, large-deep, small-shallow, small-deep pools present.   |    |    |    | Majority of pools are large-deep very few shallow.  |    |    |    | Shallow pools much more prevalent than deep pools.   |                         |    |   | Majority of pools small-shallow or pools absent.   |   |   |   |   |   |   |   |
| SCORE  | 20  | 19 | 18 | 17 | 16  | 15 | 14 | 13 | 12   | 11                      | 10 | 9 | 8  | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |   |    |    |    |   |    |    |    |  |                         |    |   |  |   |   |   |   |   |   |   |
| <b>4. Sediment Deposition</b>                  | Sediment deposition affects less than 20% of stream bottom in quiet areas. New deposition on islands and point bars is absent or minimal.   |    |    |    | Some new increase in bar formation, mostly from gravel, sand or fine sediment; 20-50% of bottom affected. Slight deposition in pools. |    |    |    | Moderate deposition of fine material on old and new bars, 50-80% of bottom affected; sediment deposits at obstructions, constrictions and bends; moderate deposition of pools. |                         |    |   | Heavy deposits of fine material, increased bar development; more than 80% of the bottom changing frequently; pools almost absent due to substantial sediment deposition. |   |   |   |   |   |   |   |
| SCORE  | 20  | 19 | 18 | 17 | 16  | 15 | 14 | 13 | 12   | 11                      | 10 | 9 | 8  | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |   |    |    |    |   |    |    |    |  |                         |    |   |  |   |   |   |   |   |   |   |
| <b>5. Channel Flow Status.</b>                 | If water backed up by obstructions ( beaver dam, log jams, bedrock during low flow) move assessment reach above or below affected area or consider postponing sampling until accurate assessment of stream can be achieved. Water reaches base of both lower banks throughout reach. Streambed is covered. Minimal productive habitat is exposed. |    |    |    | Water covers > 75% of streambed and/or < 25% of productive habitat is exposed.  |    |    |    | Water covers 25-75% of streambed and/or stable habitat is mostly exposed.  |                         |    |   | Very little water in channel and mostly present as standing pools. Little or no productive habitat due to lack of water.   |   |   |   |   |   |   |   |
| SCORE  | 20  | 19 | 18 | 17 | 16  | 15 | 14 | 13 | 12   | 11                      | 10 | 9 | 8  | 7 | 6 | 5 | 4 | 3 | 2 | 1 |
| <b>Comments</b>                                |   |    |    |    |   |    |    |    |  |                         |    |   |  |   |   |   |   |   |   |   |

### **Criteria for Taxonomic experts**

(adapted from the Taxonomic Certification Program established in 2004 by the North American Benthological Society).

In order to be considered an expert an individual must meet **at least four** of the following criteria:

1. **Authorship.** Is an author/coauthor of two or more peer-reviewed publications in the group for which the applicant seeks recognition as a taxonomic/systematic expert. Or, has prepared and presented two or more papers at professional meetings focusing on the taxonomy/systematics of the group for which the applicant seeks recognition as a taxonomic expert.
2. **Academic Qualification.** Has been presented and earned a graduate degree (MS/PhD) related to the field of invertebrate taxonomy, with MS or PhD thesis focused on the taxonomy/systematics of group for which the applicant seeks recognition as a taxonomic expert. Post-doctoral employment/experience focusing on taxonomy/systematics of group for which the applicant seeks recognition as a taxonomic expert will fulfill this criterion.
3. **Employment.** Currently serves (or has previously served) in a professional capacity (e.g., at place of employment - institution, business, agency, department, company) as curator or manager of an invertebrate collection (one or more groups) including that for which the applicant seeks recognition as a taxonomic/systematic expert.
4. **Experience.** Has a history of / currently is performing taxonomic identification / verification services for individuals, businesses, agencies, companies, and/or organizations outside of primary place of employment in the group for which the applicant seeks recognition as a taxonomic/systematic expert.
5. **Teaching.** Has organized, prepared, and successfully presented one or more taxonomic training workshops focusing on the group for which expertise is sought; the workshop or course must have been inclusive of the group for which the applicant seeks recognition as a taxonomic/systematic expert. Or, has served as an individual or as a collaborative instructor in the teaching of one or more college or university courses focusing on the taxonomy of one / several group(s) of aquatic macroinvertebrates; the course must have been inclusive of the group for which the applicant seeks recognition as a taxonomic/systematic expert.
6. **Influence and Recognition.** Has served / currently is serving as a peer-reviewer for one or more manuscripts received from a journal editor prior to its publication in the primary literature, with focus of the manuscript(s) on the group for which taxonomic expertise is sought. Service as a guest or assistant editor for a journal publishing peer-reviewed articles focusing on taxonomic / systematic issues shall satisfy this criterion.

- 7. Research.** Has submitted (as PI, co-PI, or collaborating researcher) one or more proposals to (currently pending at time of request for recognition as expert) or has received research funds (grant/contract/gift) from provincial, federal, state, regional, and/or private sources that support taxonomic/systematic studies in the group for which the applicant seeks recognition as a taxonomic/systematic expert.

## **TAXONOMIC SPECIALISTS USED FOR REFERENCE VERIFICATIONS**

**Note only those designated current are still available for verifications**

### **Oligochaeta**

Deedee Kathman, PhD (Current)  
5125 Rock Bridge Lane  
Thompson Station, TN 7692  
Phone 615-790-7692

Michael R. Milligan (deceased)  
Center for Systematics and Taxonomy  
Sarasota, FL

### **Decapoda**

Horton H. Hobbs, III, PhD  
Wittenberg University Department of Biology  
Springfield, OH

### **Mollusca**

Art Bogan, PhD  
N.C. State Museum of Natural Sciences  
Raleigh, NC

### **Odonata**

Ken J. Tennessen, PhD (Current)  
PO Box 585  
125 North Oxford Street  
Watauma, WI 54982  
256-766-6970

## **Megaloptera**

Don C. Tarter, PhD (retired)  
Marshall University Department of Biological Science

## **Hemiptera**

Cecil L. Smith, PhD  
The University of Georgia Museum of Natural History

## **Coleoptera**

Paul J. Spangler, PhD  
Dept. of Entomology  
National Museum of Natural History, Smithsonian Institute

Paul K. Lago, PhD  
The University of Mississippi

## **Ephemeroptera**

Boris C. Kondratieff, PhD (current)  
Dept. of Bioagricultural Sciences and Pest Management  
Colorado State University  
Fort Collins, Co 80523

## **Plecoptera**

Ken W. Stewart, PhD (current)  
University of North Texas  
P.O. Box 305220  
Denton, TX 76203-5220  
stewart@unt.edu  
940-565-3618

## **Trichoptera**

John C. Morse, PhD (current)  
Department of Entomology, Clemson University  
Long Hall  
Box 340365  
Clemson, SC 29634-0365  
jmorse@clemson.edu  
864-656-5049

## **Lepidoptera**

M. Alma Solis, John W. Brown, Michael G. Pogue (current)  
Systematic Entomology Laboratory, Communications & Taxonomic Services Unit  
Bldg. 046, Rm. 101, BARC-West  
10300 Baltimore Avenue  
Beltsville, MD 20705-2350  
301-504-7041  
asolis@sel.bare.usda.gov

## **Chironomidae**

John H. Epler, PhD (current)  
461 Tiger Hammock Rd.  
Crawfordville, FL 32327
