1.0 Introduction

1.1 Background

Eastman Chemical Company (Eastman) operates a large manufacturing facility in Kingsport, Tennessee (the Eastman Facility) with coal-fired and natural-fired boilers. The terrain in this area features valleys and complex terrain ridges oriented WSW to ENE. A monitor in the vicinity of Tennessee Operations indicated attainment with the 1996 SO_2 National Ambient Air Quality Standards (NAAQS) until the promulgation of a much stricter 1-hour standard of 75 ppb in 2010. The area within 3 km of the facility has been included in a designated SO_2 non-attainment area[1].

In anticipation of the need to conduct a refined dispersion modeling analysis of their facility's SO_2 emissions, Eastman initiated a comprehensive meteorological and air quality monitoring study in 2012 and 2013.

This report documents a modeling analysis with the latest version of AERMOD (version 116216r) and EPA-approved techniques in the December 2016 release of the updated 40 CFR 51 Appendix W (urban characterization for a large industrial area and the ADJ_U* low wind option). Additional modeling cases have been incorporated into this analysis to respond to EPA comments on the December 2016 modeling analysis. The revised modeling results using a lower combined emission limit for the three main Eastman stacks predict attainment of the SO_2 NAAQS within the Sullivan County non-attainment area notwithstanding future allowable SO_2 emissions from sources at the Eastman Facility.

1.2 Application of AERMOD for Kingsport, TN

A 14-month meteorological program, conducted from April 1, 2012 through May 31, 2013[2], involved a site-specific installation and operation of a 100-m tower and Doppler SODAR system to provide profiles of meteorological data as input to AERMOD for modeling the SO_2 emissions from the Eastman Facility powerhouses.

Due to further development of the use of AERMOD run in the urban mode for highly industrialized areas (proposed revisions to Appendix W in 2015[3] and also documented in a 2016 peer-reviewed paper[4]), AECOM selected the urban dispersion characterization option. The modeling approach involves the following options:

---

[1] August 5, 2013 Federal Register notice, 78 FR 47204.

[2] The monitoring started in mid-March 2012 in a "shakedown" period, and final calibrations and shut down occurred in early June, 2013.

[3] 80 FR 45340, July 29, 2015. The final rule is expected to be available at www.epa.tov/scram001 in mid-to-late December 2016.

[4] Paine, R., Warren, L.L., Moore, G.E., Source Characterization Refinements for Routine Modeling Applications, *Atm. Env.* 129 (2016), 55-67. doi: 10.1016/j.atmosenv.2016.01.003.

- Urban dispersion with an effective population of 200,000
- Use of the ADJ_U* option, but with the observed turbulence data withheld from the modeling.

This report documents through AERMOD modeling that the planned SO_2 emission reductions at the 253 powerhouse and specific emission limits applied to the coal-fired boilers at Buildings 83 and 325 will result in future SO_2 NAAQS attainment within the Sullivan County, TN SO_2 nonattainment area.

1.3 Organization of Report

Section 2 describes the Eastman Facility's emission points in detail. Section 3 describes the meteorological and monitoring field program between April 1, 2012 and March 31, 2013 and how the meteorological data were processed for input to AERMOD. The modeling set-up procedures are discussed Section 4. Application of the modeling approach to determine the "critical emission value", the use of the SO_2 emission distributions for the stacks associated with boilers 18-22, 23-24, and 30-31 to determine a rolling 30-day emission limit applicable to the total emissions of these three stacks is discussed in Section 5.

2.0 Eastman Chemical Company's Kingsport, TN Facility

2.1 Eastman Facility Setting

Eastman operates coal-fired boilers that constitute major SO_2 sources. The SO_2 emissions come from three main boiler groups that are shown in Figure 2-1: two B-83 stacks are about 70 m high, five B-253 stacks[5] are about 76 m high, and the B-325 stack is about 114 m high.

Kingsport is located in the northeast corner of Tennessee, and shares an airport (Tri-Cities) with regional cities of Johnson City and Bristol. This portion of Tennessee includes parts of three major geological formations: the Blue Ridge Mountains on the border with North Carolina in the east, the main Appalachian Mountains with the ridge and valley system (where Kingsport is located), and the Cumberland Plateau toward central Tennessee. The topography of the area is shown in Figure 2-2, which indicates that Kingsport is in a valley between ridges. The wind rose from the Tri-Cities airport, shown in Figure 2-3, reflects the general WSW-ENE alignment of the terrain features and the channeling of the winds accordingly. Figure 2-2 indicates that a prominent terrain feature to the west of Kingsport is Bays Mountain.

2.2 History of SO_2 Monitoring in Kingsport, TN

Before the 2012-2013 field study, historical SO_2 monitoring data had been taken from up to four stations, as shown in Figure 2-4. From that information, it was determined that the peak short-term monitored concentrations at the RNR monitor (AIRS ID 47-163-0007) were as high or higher than those at the other monitors, so that monitor was maintained to the present day while the others were eventually shut down. Until the 1-hour SO_2 NAAQS went into effect, the monitored concentrations indicated compliance with the pre-existing standards. However, due to the stringency of the new standard, the monitoring data indicated concentrations that are above the 1-hour SO_2 NAAQS. The 2009-2011 99^{th} percentile peak daily 1-hour maximum concentration, averaged over the 3 years (the "design concentration") was 196 ppb[6], which is greater than the NAAQS of 75 ppb.

2.3 SO_2 Emissions from Eastman Boiler Complexes

Each of the five stacks at the 253 Powerhouse serves an individual boiler (Boilers 25 – 29, refer to Figure 2-1) which provide steam and electricity to the Eastman Facility. These boilers, installed during the 1960s and 1970s, were designed as coal-fired boilers and equipped with electrostatic precipitators for particulate matter control. Eastman is implementing a project to convert each of these to natural gas combustion, in conjunction with the State of Tennessee's State Implementation Plan for the Best Available Retrofit Technology (BART) implementation as part of the Regional Haze Rule[7]. To date, three of the five boilers have been converted to natural gas and Eastman will convert the final two in

---

[5] As of December 2016, three of the five boilers were converted to natural gas.

[6] As reported in EPA's Technical Support Document for the Tennessee non-attainment designations, available at http://www.epa.gov/air/sulfurdioxide/designations/tsd/04_TN_tsd.pdf.

[7] The first of five boilers was converted to natural gas in April 2014 and the second and third boilers converted during 2016.

2018. More specifically, none of the 253 Powerhouse boilers will combust coal after the October 2018 period for implementation of controls to address the SO_2 non-attainment area.[8]

The stack at the 325 Powerhouse serves two coal-fired boilers, Boiler 30 and Boiler 31, and is modeled as a single emission source due to combined exhaust streams in a single stack. Boiler 30 is equipped with a spray dryer absorber and electrostatic precipitator to control particulate matter and acid gases. Boiler 31 is equipped with a spray dryer absorber and fabric filter to control particulate matter and acid gases.

Stack B at the 83 Powerhouse serves five coal-fired boilers (Boilers 18 – 22) and Stack C serves two coal-fired boilers (Boilers 23 and 24). Hence, two emission sources are modeled for the 83 Powerhouse. All of the 83 boilers are equipped with electrostatic precipitators for particulate matter control.

These fourteen boilers, along with three other backup natural gas-fired boilers with negligible SO_2 emissions (B-423), provide process steam and most of the electrical power needed to operate Tennessee Operations. The combination of boilers and boiler operating loads at any given time depends on manufacturing demands along with availability of boilers as each boiler has annual scheduled shutdowns. Table 2-1 lists the locations (UTM, NAD27) and stack characteristics for the eight modeled emission sources during the one year study period (2012-2013).

Figure 2-1: Power Houses at the Eastman Kingsport, TN Complex

[8] Eastman plans to cease coal-combustion at the last coal-fired boiler in the 253 Powerhouse on October 1, 2018.

325	30-31	361800.0	4042105.0	367.7	114.3	3.05

2.4 Regional SO_2 Emission Sources

EPA's final Technical Support Document[3] for the Tennessee non-attainment designations indicated that there are few additional SO_2 emission sources in the vicinity of the Eastman Facility. Recent guidance provided by EPA has indicated that the modeled local sources to be added to the evaluation modeling should include a Domtar source as well as a tail-gas incineration unit operated by Eastman. Since these sources have relatively low SO_2 emissions, AECOM included them using peak or allowable emission rates. The flat glass manufacturer (Heritage Glass) was shut down during the evaluation study period, but this source was planned for reactivation and is included in the future case compliance modeling in the event of its reactivation[9]. Stack parameters and constant emission rates for these sources are provided in Table 2-2. All the SO_2 sources are shown in Figure 2-5.

2.5 Planned SO_2 Reductions at Eastman

Eastman is in the process of making reductions in SO_2 emissions at the Kingsport plant in accordance with Best Available Retrofit Technology (BART) requirements as well as the SO_2 non-attainment designation. The reductions involve a fuel switch from coal firing to natural gas firing in all five of the boilers at the B-253 boiler complex. Table 2-3 lists the proposed reduced emissions and stack parameters for the 253 Powerhouse. This reduction is expected to reduce total plant SO_2 emissions to about 1/3 of the current levels. Due to low emissions from regional SO_2 sources (and, thus a low background concentration, as noted by the monitoring), this reduction would be expected to result in a future monitored concentration that is below the NAAQS because the currently monitored design concentration is less than 3 times the NAAQS. The field study used to provide the meteorological data for the current modeling and the associated SO_2 monitoring program is described in the next section.

[9] As of January 2017, the plans for reactivation have not gone forward. Nevertheless, inclusion of this source ensures that even an unlikely reactivation will not adversely impact the model results.

Table 2-2: Additional Modeled Nearby SO_2 Source Emissions and Stack Parameters

						Emissions		
Source	UTM-X (m)	UTM-Y (m)	Base Elev. (m)	Stack Ht. (m)	Stack Diam. (m)	Emission Rate (g/s)	Stack Temp. (K)	Exit Velocity (m/s)

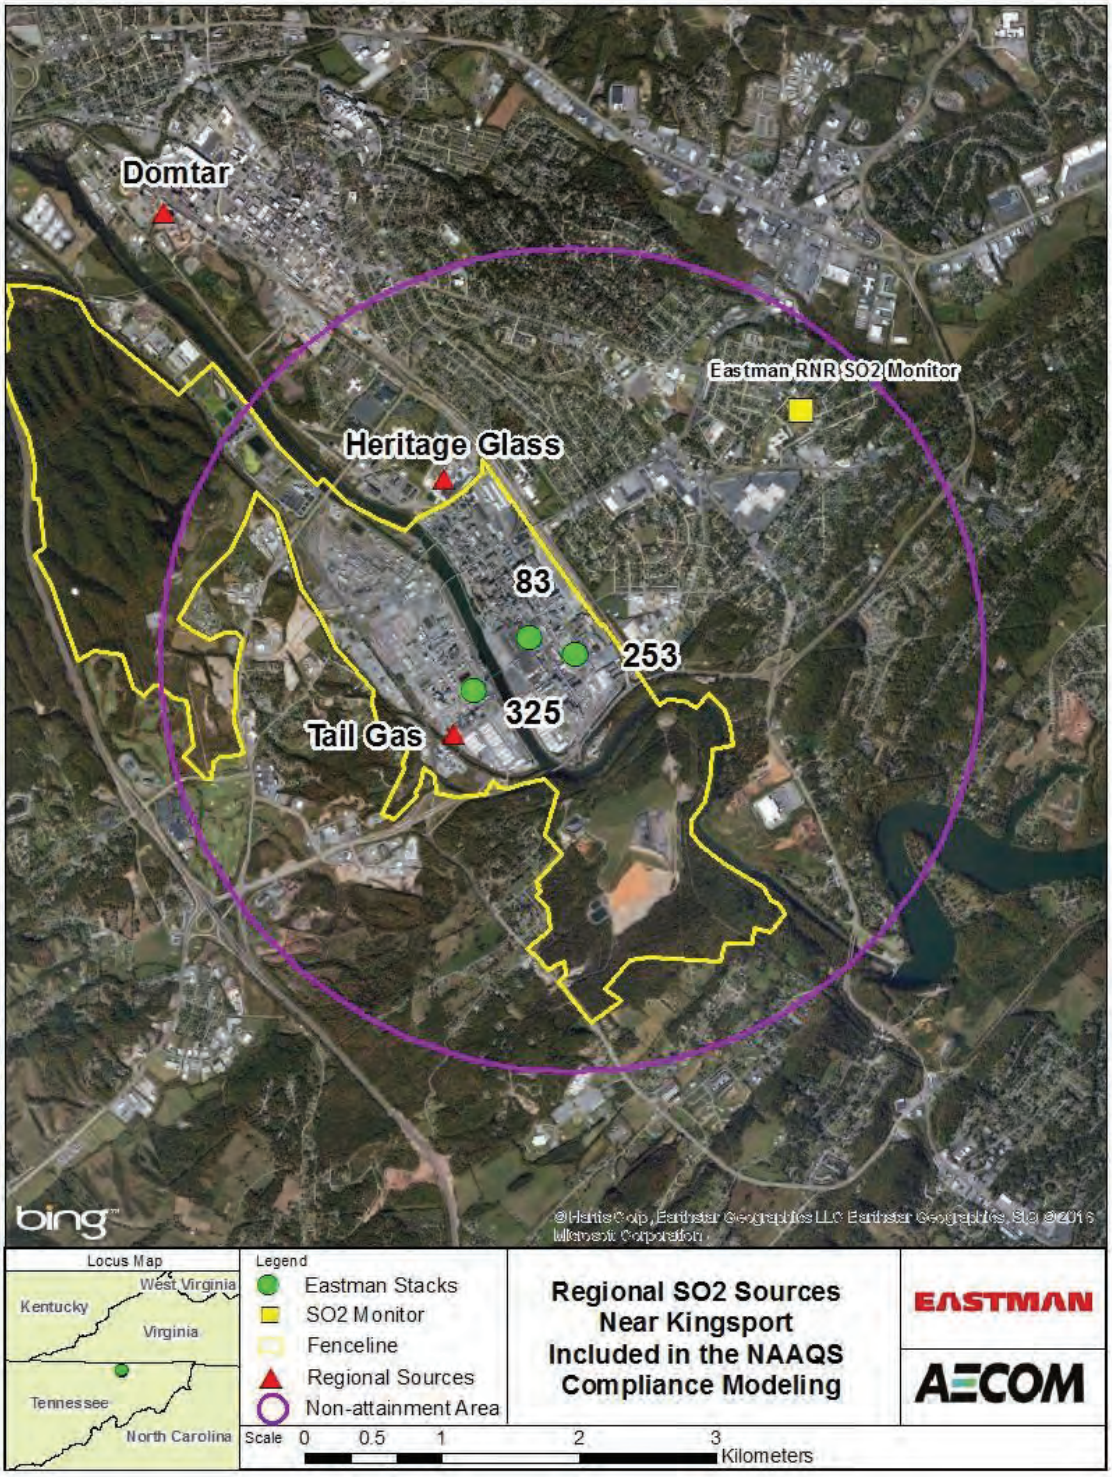
Figure 2-5: Regional SO_2 Sources Near Kingsport Included in the NAAQS Compliance Modeling



3.0 Overview of the Site-specific Meteorological Database

3.1 Meteorological Monitoring Network Design

Eastman engaged AECOM to assist with a site-specific database to support a dispersion model with unbiased model predictions. AECOM determined from a review of the sources and topography in the area that EPA's guideline model, AERMOD[10], would likely be the first choice for the model to consider. Due to the complex terrain in the area, AECOM recommended that Eastman acquire multiple-level meteorological data for input to AERMOD, based upon previous sensitivity studies[11] in terrain settings and EPA's use of site-specific data in its evaluation[12] of AERMOD. Eastman first presented this general approach to TDEC and EPA Region 4 representatives in a meeting held in Atlanta on October 31, 2011.

The resulting plan for meteorological measurements led to the installation of a 100-meter meteorological tower equipped with multiple levels of meteorological sensors (at 2, 10, 50, and 100 m) and a Sound Detection And Ranging (SODAR) wind profiler system (with measurements starting at 50 m and extending upward in 50-m increments to 500 m). The data collected by these instruments was used as input to AERMOD, which was developed to accommodate multiple levels of meteorological data to more accurately predict vertical profiles of meteorological variables used in the modeling. For the monitoring program, the EPA Guidelines for Air Quality Modeling (40 CFR Part 51, Appendix W[13]) and EPA's meteorological monitoring guidance[14] provided the general guidance for sensor and parameter selection and siting of the tower and SODAR.

Eastman submitted a quality assurance plan for the meteorological monitoring to TDEC and EPA on January 5, 2012. Comments were received from both TDEC and EPA, and Eastman submitted a revised (final) plan along with responses to comments received to the agencies on February 22, 2012. Eastman received no further agency comments and thereafter put the meteorological monitoring network into operation officially on April 1, 2012, after a few days of "shakedown" operation.

Table 3-1 provides a list of the meteorological parameters included in the field study. As indicated in the monitoring plan reviewed by TDEC and EPA, input to AERMET consisted of parameters measured on the 100-m tower up to the 100-m level, and at incremental 50-m levels from 150 m to

[14] U.S. EPA. Meteorological Monitoring Guidance for Regulatory Modeling Applications. Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina. EPA 454/R 99 005. February 2000. Available at http://www.epa.gov/scram001/guidance/met/mmgrma.pdf.

500 m from the SODAR. SODAR data from the 50-m and 100-m levels were available for comparison to the tower data for quality assurance purposes. An independent audit of the meteorological measurements was conducted by Air Resources Specialists, Inc. in May, 2012. Their audit report, issued May 25, 2012, indicated that all meteorological instruments were within EPA-recommended accuracy goals, and that there were no adverse findings from the audit. Representatives of TDEC and EPA visited the site on December 11, 2012. Eastman representatives presented further updates regarding the site-specific measurement program to TDEC and EPA on March 18, 2013. Eastman representatives advised TDEC and EPA representatives in the December 2012 and March 2013 meetings that Eastman was testing site-specific modeling options and that the default AERMOD model significantly over-predicted SO_2 emissions impacts. .

3.2 Meteorological Tower Data Capture Summary

The meteorological tower parameters generally had data captures above 90% for each month of the monitoring program. One exception is that for the months of July and August, 2012, data capture for precipitation was less than 90% due to a mechanical failure of the rain gauge. In December, 2012, foreign debris, i.e., vegetation, in the rain gauge also resulted in data capture below 90%. Each of the other months had data captures above 90% for precipitation, which was principally used to provide quality assurance for the SODAR data review.

The data capture for the April 2012-March 2013 measurement period for the meteorological tower parameters was above 90% (and often at 100%) for each parameter. Table 3-1 shows the data capture for all the parameters measured on the meteorological tower.

3.3 SODAR Data Capture Summary

AERMOD accepts data from multiple levels, and the measurement program was designed to accommodate the tower data with supplemental data from the SODAR. Data capture for the SODAR data was generally 90% or greater up to around 400 meters except for portions of the first quarter of 2013, as described further below. Table 3-2 shows the data capture for all the parameters measured by the SODAR.

The SODAR data capture was reduced (lower range of values) during certain portions of the measurement period due to natural events and noise interference issues. In the middle of April 2012, a severe rain event damaged the system, resulting in data captures below 90% for the month. Components of the SODAR system were replaced on April 19, 2012, which resulted in a marked improvement in the data capture for each parameter. Other periods during portions of January-February 2013 had some reductions in data capture attributed to new building construction in the area, likely causing noise interference. This issue was finally resolved in early March 2013 by a combination of rotating the SODAR antenna table and other system adjustments.

3.4 Total System Data Capture

The 2012 monitoring plan reviewed by TDEC and EPA Region 4 had the following language to describe the acceptability of each hour's meteorological data for modeling purposes:

"The following criteria will be applied to determine whether an hour of the on-site data is counted as available for purpose of data capture:

- Wind direction, wind speed, and temperature must each be available for a given hour. These variables are used in the meteorological pre-processor to compute the atmospheric stability and other related micrometeorological parameters.
- Each of these parameters must be present from at least one of the three tower levels (10, 50, or 100 meters) or from the 50-m and/or 100-m SODAR levels; they need not be all present from the same level.
- If the SODAR is reporting missing data, but at least one tower level is reporting, then that hour is still acceptable."

Based upon these criteria, the meteorological monitoring program easily met the 90% data availability for modeling purposes, as shown in Table 3-3. In fact, the meteorological tower had 3 levels of wind and temperature available nearly 100% of the time, and had supplemental SODAR data at four additional levels (up to 300 m) at least 85% of the time. Given the completeness of the meteorological tower data, the overall data coverage for the weather station was at or near 99+% per quarter for the meteorological parameters processed for the AERMOD modeling. Data from the 50-m and 100-m levels of the SODAR were not used in the modeling, but were used in performance testing of the SODAR against the meteorological tower.

Table 3-3: Overall Data Capture Summary by Quarter for Model Input with Onsite Meteorological Data

	Apr[1] 2012	May 2012	Jun 2012	1st Qtr	Jul 2012	Aug 2012	Sep 2012	2rd Qtr
% hours with data available for modeling	99.8	100.0	100.0	99.9	100.0	100.0	99.8	99.9

	Oct 2012	Nov 2012	Dec 2012	3th Qtr	Jan 2013	Feb 2013	Mar 2013	4th Qtr	Cum Avg.
% hours with data available for modeling	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

Note: only four hours were missing over the entire year (two hours each in April and September, 2012) due to tower calibration activities.

3.5 Meteorological Data Processing

To prepare the on-site meteorological data for model input, the raw data needed to be extracted and formatted for use in the AERMET (version 16216) pre-processor. There are two separate sets of data. Meteorological measurements taken at the 100-m tower were made at 4 levels: 2 m, 10 m, 50 m, and 100 m. A nearby SODAR collected upper level data at 50-m increments up to the 500-700 m range. For the modeling, validated hourly[15] data were used from the SODAR from the 150-m level up to the 700-m level[16]. The sparseness of data above 700 m restricted its use in the modeling.

In recent EPA Modeling Clearinghouse concurrence memoranda, EPA has indicated concerns over the inclusion of turbulence measurements in on-site meteorological data when using low wind model options. On August 1, 2016, EPA stated[17] that,

> "While not an issue in this particular case, we continue to evaluate the potential that the use of the ADJ_U* Beta option in combination with site-specific meteorological data that includes the sigma-theta and/or sigma-w turbulence parameters may introduce a bias toward concentration underprediction and caution anyone considering the use of both the ADJ_U* Beta option and meteorological data that includes the derived sigma-theta and/or sigma-w turbulence parameters in regulatory applications without consultation and approval from the appropriate permitting authority and the respective EPA Regional Office."

Finally, with the promulgation of Appendix W changes published in the January 17, 2017 *Federal Register* (82 FR 5182), the ADJ_U* option does not require case-by-case approval if on-site turbulence measurements are omitted from the modeling. For these reasons, we did not include sigma-theta and sigma-w turbulence parameters in the Eastman SO_2 modeling.

For all meteorological data parameters, the hourly-averaged values reported by the data loggers were used as input to AERMET. For modeling purposes, no replacements of calms were done on the meteorological tower winds that recorded speeds below the wind vane starting threshold level of 1 mph (0.45 m/s). AERMET takes into account winds that are below a threshold value consistent with the instrument characteristics. For values of the standard deviation of vertical velocity (sigma-w) that were below a starting instrument threshold value of 0.1 m/s, those values were set to missing[18].

The meteorological database used for the model evaluation was also used for this NAAQS compliance modeling. EPA and TDEC have already thoroughly reviewed the model evaluation database.

---

[15] Starting in September 2012, 15-minute sub-hourly data were also collected for a few months.

[16] After the change in September 2012 to sub-hourly data, SODAR data was archived up to the 500-m level.

[17] EPA Model Clearinghouse memo for Region 8, available at https://cfpub.epa.gov/oarweb/MCHISRS/index.cfm?fuseaction=main.resultdetails&recnum=16-VIII-01.

[18] The starting speed of the vertical wind vane was 0.3 m/s. As per guidance in the SCIPUFF Technical Documentation, 2008. "A typical value for the vertical velocity variance, (sigma-w)^2, is $0.01 m^2 s^{-2}$ and a typical vertical length scale, lambda-V, is 10m. We suggest using these values for all locations above the boundary layer." This implies a minimum sigma-w of 0.1 m/s. (p 194).

3.6 Model Information

The air dispersion modeling was performed using EPA's preferred air dispersion model AERMOD (version 16216r). AERMOD is a steady-state plume model that calculates air dispersion based on planetary boundary layer turbulence structure and scaling concepts. AERMOD is listed as a recommended model in Appendix W of 40 CFR Part 51 for determining compliance with National Ambient Air Quality Standards and other regulatory requirements. Supporting EPA processors utilized in this application include: the downwash processor BPIP (version 04274); the terrain processor AERMAP (version 11103); and the meteorological processors AERSURFACE (version 13016) and AERMET (version 16216).

The meteorological data reported by the 100-m tower are scalar averages, but those from the SODAR are vector averages. Due to the large percentage of hours for which SODAR data was available, the VECTORWS option was selected in AERMOD.

The dispersion modeling analysis was conducted using AERMOD model with the AERMET low wind speed adjustment, "ADJ_U*". In a final rule signed by the EPA Administrator on December 20, 2016 and published in the January 17, 2016 Federal Register (featuring an updated 40 CFR Part 51 Appendix W)[19], EPA implemented refinements to its preferred short-range model, AERMOD, involving low wind conditions. One of these refinements involves an adjustment to the computation of the friction velocity ("ADJ_U*") in the AERMET meteorological pre-processor. Beginning with version 16216, the ADJ_U* option is no longer a beta option when processing onsite data with no turbulence data.

3.7 Meteorological Processing: Surface Characteristics

Fourteen months of the on-site meteorological data was processed with AERMET, the meteorological preprocessor for AERMOD, which is consistent with guidance stated in 9.3.1.2 of 40 CFR Part 51, Appendix W (EPA modeling guidelines). The meteorological data required for input to AERMOD was created with the latest version of AERMET (16216). AERMET creates two output files for input to AERMOD:

- SURFACE: a file with boundary layer parameters such as sensible heat flux, surface friction velocity, convective velocity scale, vertical potential temperature gradient in the 500-meter layer above the planetary boundary layer, and convective and mechanical mixing heights. Also provided are values of Monin-Obukhov length, surface roughness, albedo, Bowen ratio, wind speed, wind direction, temperature, and heights at which measurements were taken.
- PROFILE: a file containing multi-level meteorological data with wind speed, wind direction, temperature, sigma-theta (σ_θ) and sigma-w (σ_w) when such data are available. For this application, the file contains data from several levels on the tower (2, 10, 50 and 100 m) and SODAR (from 150 m through 700 m, at 50-m increments). As discussed above, sigma-theta and sigma-w turbulence parameters were omitted from this modeling.

AERMET requires specification of site characteristics including surface roughness (z_o), albedo (r), and Bowen ratio (B_o). These parameters were developed according to the guidance provided by EPA in the AERMOD Implementation Guide (AIG)[20].

---

[19] Available at https://www3.epa.gov/ttn/scram/appendix_w-2016.htm

[20] Available in the AERMOD documentation at http://www.epa.gov/ttn/scram/dispersion_prefrec.htm#aermod.

The AIG provides the following recommendations for determining the site characteristics:

1. The determination of the surface roughness length should be based on an inverse distance weighted geometric mean for a default upwind distance of 1 kilometer relative to the measurement site. Surface roughness length may be varied by sector to account for variations in land cover near the measurement site; however, the sector widths should be no smaller than 30 degrees.
2. The determination of the Bowen ratio should be based on a simple un-weighted geometric mean (i.e., no direction or distance dependency) for a representative domain, with a default domain defined by a 10-km by 10-km region centered on the measurement site.
3. The determination of the albedo should be based on a simple un-weighted arithmetic mean (i.e., no direction or distance dependency) for the same representative domain as defined for Bowen ratio, with a default domain defined by a 10-km by 10-km region centered on the measurement site.

The AIG recommends that the surface characteristics be determined based on digitized land cover data. EPA has developed a tool called AERSURFACE that can be used to determine the site characteristics based on digitized land cover data in accordance with the recommendations from the AIG discussed above. AERSURFACE incorporates look-up tables of representative surface characteristic values by land cover category and seasonal category. AERSURFACE was applied with the instructions provided in the AERSURFACE User's Guide.

The latest version of AERSURFACE (Version 13016) supports the use of land cover data from the USGS National Land Cover Data 1992 archives[21] (NLCD92). The NLCD92 archive provides data at a spatial resolution of 30 meters based upon a 21-category classification scheme applied over the continental U.S. The AIG recommends that the surface characteristics be determined based on the land use surrounding the site where the surface meteorological data were collected.

As recommended in the AIG for surface roughness, the 1-km radius circular area centered at the meteorological station site was divided into 12 sectors for this analysis (see Figure 3-2).

In AERSURFACE, the various land cover categories are linked to a set of seasonal surface characteristics. As such, AERSURFACE requires specification of the seasonal category for each month of the year. The following five seasonal categories are supported by AERSURFACE, with the applicable months of the year specified for this site.

1. Midsummer with lush vegetation (June-August).
2. Autumn with un-harvested cropland (September- November).
3. Late autumn after frost and harvest, or winter with no snow (December, January, and February).
4. Winter with continuous snow on ground (none; based on the Tri-City Regional Airport records).
5. Transitional spring with partial green coverage or short annuals (March-May).

[21] http://edcftp.cr.usgs.gov/pub/data/landcover/states/

For Bowen ratio, the land use values are linked to three categories of surface moisture corresponding to average, wet, and dry conditions. The surface moisture condition for the site may vary depending on the meteorological data period for which the surface characteristics will be applied. AERSURFACE applies the surface moisture condition for the entire data period. Therefore, if the surface moisture condition varies significantly across the data period, then AERSURFACE can be applied multiple times to account for those variations. As recommended in the AERSURFACE User's Guide, the surface moisture condition for each month was determined by comparing the on-site precipitation for the period of data to be processed to the 30-year climatological record (Tri-City Regional Airport), selecting "wet" conditions if precipitation is in the upper 30th percentile, "dry" conditions if precipitation is in the lower 30th percentile, and "average" conditions if precipitation is in the middle 40th percentile. The 30-year precipitation data set used in this modeling was taken from the National Climatic Data Center. The monthly designations of surface moisture input to AERSURFACE are summarized in Table 3-4.

Table 3-4: Bowen Ratio Categories for the On-site Meteorological Tower

Month	Bowen Ratio Category	
	2012	2013
April	Average	--
May	Dry	--
June	Dry	--
July	Wet	--
August	Dry	--
September	Wet	--
October	Average	--
November	Dry	--
December	Dry	--
January	--	Wet
February	--	Dry
March	--	Average
April	--	Average
May	--	Average

3.8 Meteorological Processing: AERMET

The processed on-site 12-level meteorological data for the merged meteorological tower (levels: 2 m, 10 m, 50 m and 100 m) and SODAR (levels: 150 m – 500 m, at 50-m increments) was entered into the stage 1 AERMET input file along with concurrent NWS surface data from the Tri-City Regional Airport National Weather Station (13877) and upper air data from Nashville, TN (13897).

The Tri-City Regional Airport is located approximately 8.5 miles east, southeast of the facility. Integrated Surface Hourly (ISH) surface data in for the April, 2012 – May, 2013 period were downloaded from the National Climate Data Center (NCDC)[22]. The Nashville airport is located 200 miles west of Kingsport and has mean mixing heights that are comparable to this location. Upper air

[22] ftp://ftp.ncdc.noaa.gov/pub/data/noaa

data was downloaded from the NOAA radiosonde observation (RAOB) website[23]. Three missing upper air 12Z hours were filled with concurrent data from the nearby Roanoke, VA upper air station (noted in a README file in the accompanying modeling archive).

The meteorological data was processed using the AERMOD meteorological preprocessor AERMET (version 16216).

The threshold wind speed for the on-site data was set to its manufacturer-specified value of 0.447 m/s (1 mph). In the stage 3 input, no NWS substitutions were performed for any hours with missing on-site wind data (which was not an issue given the high data coverage of the meteorological tower).

The AERMET was used with the ADJ_U* option and omissions of turbulence data (σ_Θ and σ_w) to process one year of meteorological data.

For a sense of the bulk wind flow near plume height, the 100-m wind rose in Figure 3-3 shows the percentage of time wind blew from each direction for the April, 2012 through March, 2013 period.

3.9 Regional Background Concentrations

To account for the impact of sources other than Eastman, it is necessary to include the contributions of any identified nearby SO_2 sources as well as distant sources that would have a relatively uniform (regional) concentration impact over the non-attainment area. The discussion in Section 2.4 provides a list of relatively minor, but nearby sources that were included in the modeling.

To account for regional background concentrations, recent guidance provided by EPA has suggested the use of ambient SO_2 concentrations from the monitor located at Mammoth Cave National Par in Kentucky (AQS ID 21-061-0501). AECOM calculated 3 years (2013-2015)of the hourly varying "season-by-hours-of-day" background dataset using procedures described in the March 1, 2011 EPA guidance [24]. The seasonal by hour of the day ambient background value was processed within the model using the BACKGRND SEASHR keyword in the source card.

Figure 3-4 shows the resultant seasonal values. Table 3-5 tabulates the same 96 values from Figure 3-4 for the modeling.

[24] This guidance is available at http://www.epa.gov/ttn/scram/guidance/clarification/Additional_Clarifications_AppendixW_Hourly-NO2-NAAQS_FINAL_03-01-2011.pdf.

4.0 AERMOD Urban/Rural, Receptor, and Building Downwash Modeling Procedures

The AERMOD model requires specific inputs, including the meteorological, terrain and building downwash data. The previous section detailed the processing of the on-site meteorological data. This section describes the processing of the receptor and building downwash information. The land use determination is also described in this section.

4.1 Urban/Rural Determination

The application of AERMOD requires characterization of the local (within 3 kilometers) dispersion environment as either urban or rural, based on an EPA-recommended procedure that characterizes an area by prevalent land use. This land use approach classifies an area according to 12 land use types. In this scheme, areas of industrial, commercial, and compact residential land use are designated urban. According to EPA modeling guidelines, if more than 50 percent of an area within a 3-km radius of the proposed facility is classified as rural, then rural dispersion coefficients are to be used in the dispersion modeling analysis. Conversely, if more than 50% of the area is urban, urban dispersion coefficients are used. Auer analysis and population density analyses were conducted to confirm that the area is urban. In addition, a procedure to estimate an effective population in the area of Eastman Facility due to excess temperature is presented in Section 4.1.3.

4.1.1 Auer Land Use Analysis

Visual inspection of the 3-km area surrounding the Eastman Facility does not give a clear distinction of whether the land use is urban or rural (see Figures 4-1). As a result, AECOM conducted an Auer analysis within a 3-km radius around the site (specifically around Powerhouse 83). The analysis, shown in Figure 4-2, determined that in 1992 the land use is more than 50% urban (33.8% high-intensity residential and industrial/commercial and 18.6% low-intensity residential). Moreover, additional urbanization has occurred since 1992, as shown in more recent images from 2001 and 2011 (Figure 4-3 b and Figure 4-3 c). The more recent digital images of land use show that some nearby residential areas and industrial area have become more populated and expanded in size since 1992. Therefore, this analysis indicates that the area within 3 km of the Eastman Facility is urban.

4.1.2 Effective Population Estimate

The Eastman Facility is located within a city with a population of about 50,000, with the facility itself having a considerably large fugitive heat release that we have accounted for in determining the “effective population” input to AERMOD. Appendix B provides the approach followed to estimate the effective population for modeling as a result of the heat releases from the facility. The results of our analyses lead to an effective population of 200,000.

Based on evidence presented above, AECOM determined that the area within 3 km of the Eastman Facility should be treated as urban. Therefore, urban dispersion option with an effective population of 200,000 was used in the modeling.

4.2 Receptor Processing

Model receptors were placed at 50-meter intervals along the fence-line, public access roads and river banks as well as in a 100-meter grid throughout the 3-km non-attainment area (Figure 4-4). The receptor spacing is consistent with a recent PSD submission to TDEC[25] and is supported by modeling guidance in other EPA Region 4 states (Georgia[26], North Carolina[27], and South Carolina[28]). Terrain elevations were developed from the National Elevation Dataset (NED) acquired from USGS[29], using the EPA's terrain processor, AERMAP (version 11103).

4.3 Building Downwash Processing

Good engineering practice (GEP) stack height is defined as the stack height necessary to ensure that emissions from the stack do not result in excessive concentrations of any air pollutant as a result of atmospheric downwash, wakes or eddy effects created by the source, nearby structures or terrain features.

A GEP stack height analysis was performed for the boiler stacks in accordance with EPA's stack height guidelines (EPA, 1985). Per the guidelines, the physical GEP height, (H_{GEP}), is determined from the dimensions of all buildings which are within the region of influence using the following equation:

$$H_{GEP} = H_B + 1.5L$$

where:

H_B = height of the structure within 5L of the stack which maximizes H_{GEP}, and

L = lesser dimension (height or projected width) of the structure.

For a squat structure, i.e., height less than projected width, the formula reduces to:

$$H_{GEP} = 2.5H_B$$

In the absence of influencing structures, a "default" GEP stack height is credited up to 65 meters.

A summary of the GEP stack height analyses is presented Table 4-1. The GEP formula stack heights for all the sources are higher than their respective stack heights. Therefore, emissions are potentially subject to building downwash and wind direction-specific building dimensions developed with the EPA's Building Profile Input Processor (BPIP-PRIME) were input to AERMOD. The BPIP input and output files are provided in the modeling archive. The locations and dimensions of the buildings/structures relative to the exhaust stacks are depicted in Figure 4-7.

Table 4-1: Summary of GEP Analysis

Emission Source	Model Source Name	Stack Height (m)	Controlling Buildings / Structures	Building Height (m)	Projected Width (m)	GEP Formula Height (m)
253 Powerhouse Sources	253_25 – 253_29	76.2	253 Powerhouse	76.2	70.0	181.0
325, Stacks 30-31	325_3031	114.3	Silos	67.1	57.0	153.0

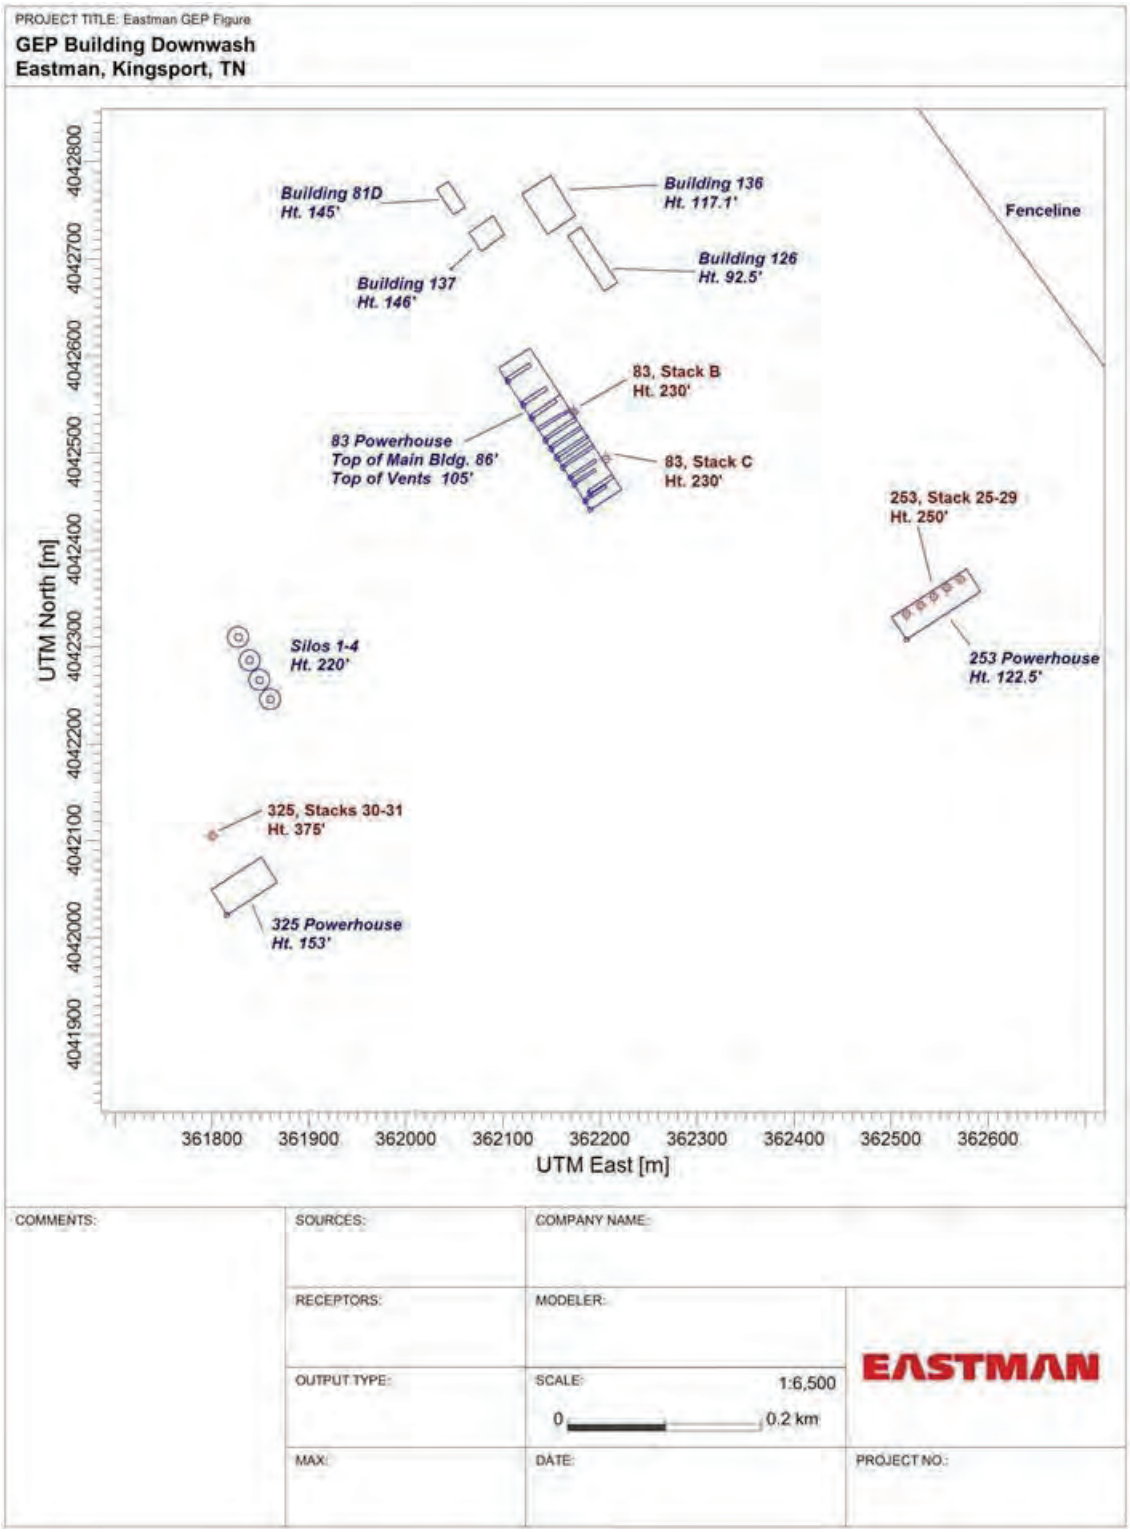
Figure 4-5: GEP Building Downwash for Eastman Chemical



5.0 Determination of Long-Term SO_2 Permit Emission Limits

The “critical emission value” for a facility is the maximum 1-hour average emission rate that, when combined with background, results in a design concentration that just complies with the NAAQS. The critical value is used as a reference point for setting a longer-term emission rate. This section describes a load analysis, critical emission values modeling approach, and the resulting long-term SO_2 permit limit for the Eastman Facility.

5.1 Load Analysis

The AERMOD modeling analysis was conducted with emission rates and exhaust characteristics (velocity and temperature) that represent a range of possible values for the Eastman 83 Powerhouse boilers 18-24 and for 325 Powerhouse boilers 30-31 during steady-state operations. The analysis evaluated 100%, 75% and 50% operating loads.

TDEC provided Eastman with a set of stack exit velocities and temperatures as a function of emission rate that we used in this analysis and in the subsequent critical emission value analysis. The TDEC analysis and our extension of the information provided to the entire range of emission rates modeled are provided in Appendix A.

For the load analysis, we used a reference high emission rate of 1,000 lb/hr (126 g/s) as a 100% load case for both the 18-22 and 23-24 boiler stacks, and scaled the emissions by percentage for the 75% and 50% load cases. For the boiler 30-31 stack, we used a reference 100% load emission rate of 400 lb/hr and scaled the emissions by load linearly. The input data for the exhaust temperature and exit velocity values were taken from the relationship documented in Appendix A, Table A-2 for each emission rate modeled.

The modeling input parameters and results of the load analysis are listed in Table 5-1. As expected, the worst- case load cases were the high load case for each stack.

Table 5-1: AERMOD Load Analysis Results

83 Power House, Boilers 18-22				
Source and Load	**Emission (g/s)**	**Temperature [2] (K)**	**Velocity [2] (m/s)**	**99th Percentile 1-hour Concentration (µg/m³)**
18-22 100% Load	126.00[1]	468.58	14.90	90.69
18-22 70% Load	94.50	461.38	12.53	77.70
18-22 50% Load	63.00	452.25	8.37	65.78
83 Power House, Boilers 23-24				
Source and Load	**Emission (g/s)**	**Temperature [2] (K)**	**Velocity [2] (m/s)**	**99th Percentile 1-hour Concentration (µg/m³)**
23-24 100% Load	126.00[1]	447.81	13.60	102.42
23-24 75% Load	94.50	439.78	11.05	89.62
24-24 50% Load	63.00	431.76	7.90	73.68
325 Power House, Boilers 30-31				
Source Name	**Emission [1] (g/s)**	**Temperature [2] (K)**	**Velocity [2] (m/s)**	**99th Percentile 1-hour Concentration (µg/m³)**
30-31 100% Load	50.40[1]	356.87	30.10	41.28
30-31 75% Load	37.80	355.57	29.71	31.63
30-31 50% Load	25.20	354.27	29.32	21.38

[1] Emission rate represents a typical high value for this stack.
[2] Temperature and velocity calculated using the equations from Appendix A.

5.2 Critical Emission Value Modeling Approach

The critical emission value is the short-term (1-hour average in this case) constant emission rate that results in a design concentration at or below the NAAQS. Based upon EPA's SO_2 nonattainment modeling guidance[30], the critical value can be used as a reference point for setting a longer-term emission rate. For the critical value run, the temperature and velocities for the 83 and 325 sources were determined using equations from Appendix A.

As noted before, with three different stacks, many different possible combinations of critical values are possible for resulting in a design concentration at or below the NAAQS. In addition, the facility load can shift among the 18-22, 23-24, and 30-31 units so that they would not be emitting at peak rates simultaneously. In this case, TDEC worked with Eastman to determine a large range of operational

[30] EPA, April 23, 2014. Guidance for 1-hour SO2 Nonattainment Area SIP Submissions, available at https://www.epa.gov/sites/production/files/2016-06/documents/20140423guidance_nonattainment_sip.pdf.

cases to model. These cases were expanded to respond to EPA comments[31], as shown in Table 5-2 (with stack parameters listed in Table 5-3), to show NAAQS compliance over all of the cases modeled. The cases modeled also included four additional cases that EPA presented in their January 18, 2017 comments, as shown in Tables 5-4 and 5-5. The precedent case for this 3-stack emissions cap is the Hillsborough, Florida SO_2 nonattainment area resolution, as documented in EPA's proposed rule.[32] In that analysis, EPA considered a range of stack operations for 1, 2, and 3 stacks, and required the modeled results to show NAAQS compliance for all cases modeled. It is noteworthy that the Eastman operations involve load shifting of production that will avoid maximum operation for units exhausted to all three stacks at the same time. This restriction was not present for the Hillsborough, Florida application.

The cases included in Table 5-2 that span a range of stack operations are as follows:

- Maximum emissions for just one stack in operation are modeled for each stack, in addition to an emissions cap for all 3 stacks. This results in 3 cases (1a, 1b, and 1c) that are applicable to stacks for boilers 18-22, 23-24, and 30-31, respectively. In reality, never is only one of these stacks in operation without at least one of the other two.

- High emissions for two stacks in operation are presented as part of the NAAQS attainment demonstration of a 3-stack emissions cap for cases to test a range of conditions for modeled attainment. Based upon operational experience, units 30-31 are never both down at the same time except in the case of a very rare forced outage of one while the other is down for maintenance. This happened only three hours during the 2013-2015 period evaluated. These units are base loaded and one must be operational to burn fuel gas generated by Eastman's production process. The same is true for units 23 and 24 (base-loaded also). These units were both down for only 20 hours during the 2013-2015 period. Units 18-22 function as "swing" units and experience their highest utilization when the base-loaded units noted above are down for annual maintenance or during forced outages. For a little over 1300 hours in the three-year period (4 percent of the time), all five of these units were down. So, while not realistic, these cases were considered to demonstrate that, even in extreme variations, the three-stack limit is protective.

- Emission cases for all three stacks in operation were also modeled as part of the NAAQS attainment demonstration. For this set of runs, emissions data from the 2013-2015 period were examined for high load operations with emissions totaling at least 1,500 lb/hr from boilers 18-24 (leaving 400 lb hour from the 30-31 stack). This examination indicated that the ratio of emissions between the 18-22 and 23-24 stacks for these cases ranged between about 0.6 (10^{th} percentile case) and 1.2 (90^{th} percentile case). We looked at several cases for three stacks in operation with emission ratios for 18-22 and 23-24 ranging from 0.6 to 1.2 in ratio steps of 0.1.

The emission rates, stack parameters, and modeling results for a grand total of 27 cases are provided in Tables 5-2 through 5-5. All 27 cases show modeled SO_2 NAAQS attainment (concentrations not exceeding 196.5 $\mu g/m^3$). Concentration isopleths for one of the typical cases with three stacks in operation, Case 3e, is shown in Figure 5-1.

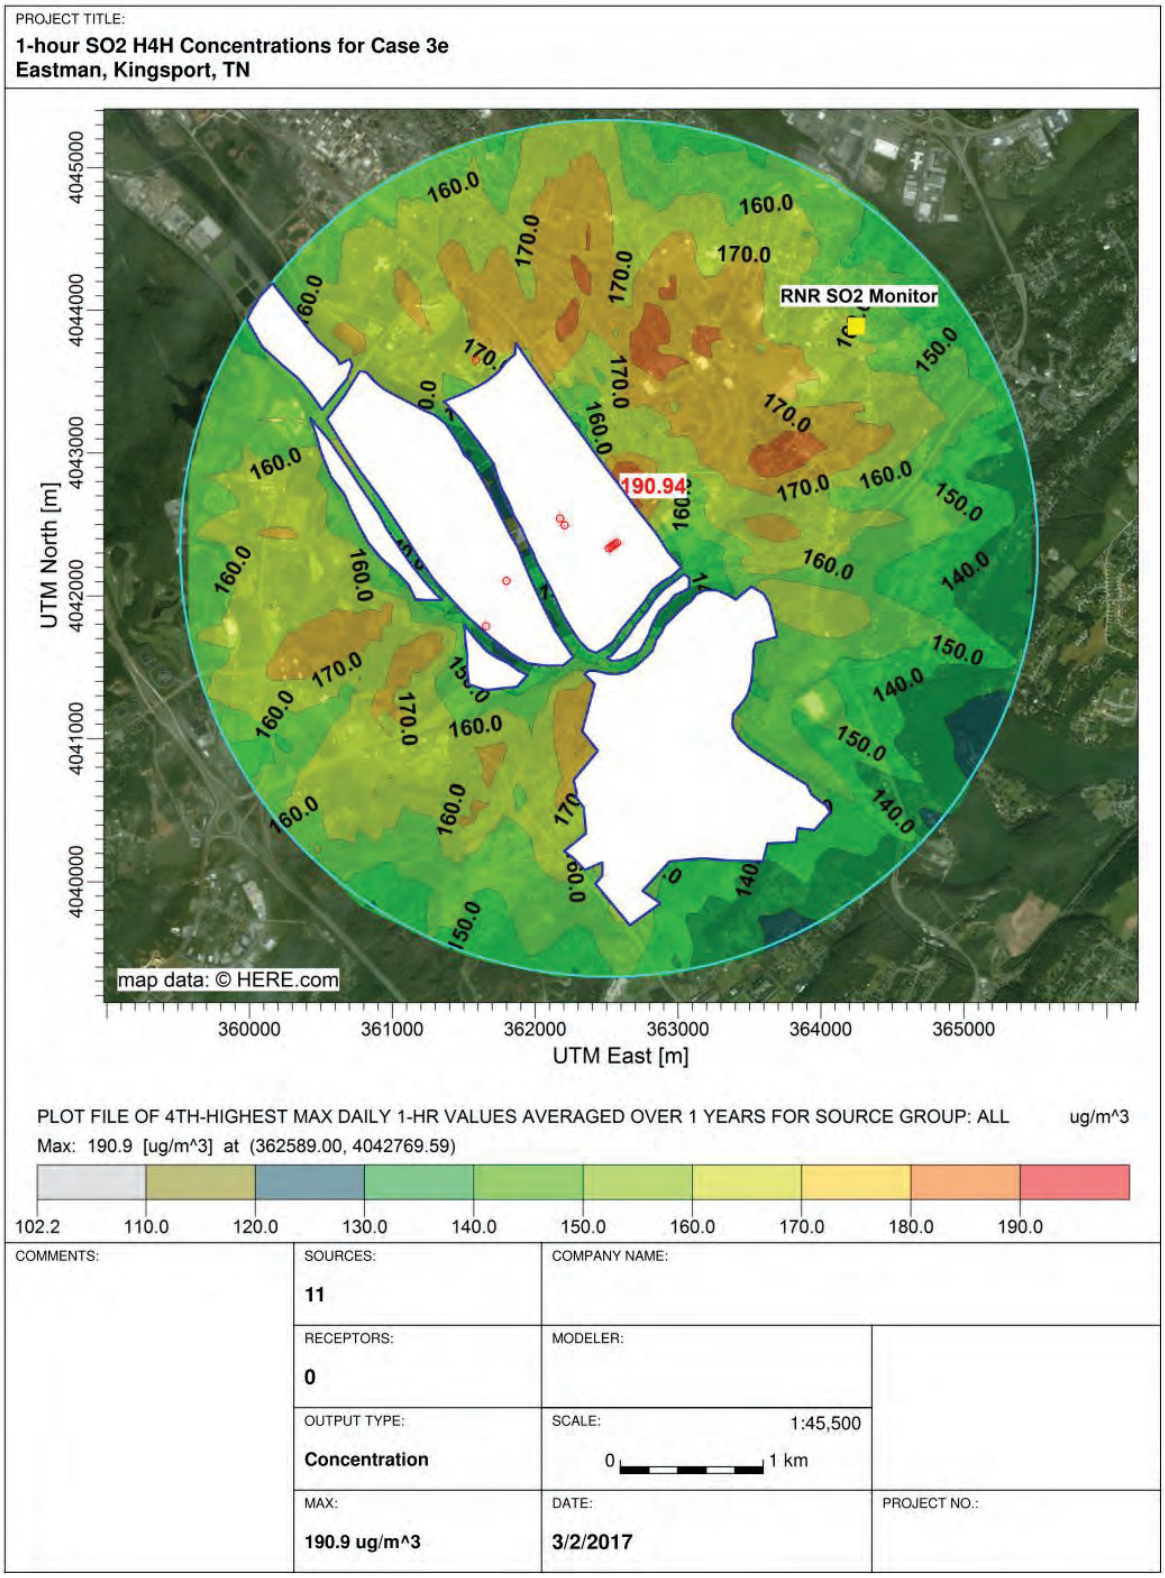
Figure 5-1: Concentration Isopleths for Case 3e



5.3 Determination of the Appropriate Long-term Average Emission Rates for Permit

EPA's April 23, 2014 guidance[33] for resolving SO_2 nonattainment areas acknowledges "that it may be possible in specific cases for states to develop control strategies that account for variability in 1-hour emissions rates through emission limits with averaging times that are longer than 1 hour, using averaging times as long as 30-days, but still provide for attainment of the 2010 SO_2 NAAQS." EPA's general expectation is that for infrequent periods of hourly emissions above the critical emission value, "these periods would be unlikely to have a significant impact on air quality, insofar as they would be very unlikely to occur repeatedly at the times when the meteorology is conducive for high ambient concentrations of SO_2. EPA considers this option to be an "appropriate balance between providing a strong assurance that the NAAQS will be attained and maintained, while still acknowledging the necessary variability in source operations and the impairment to source operations that would occur under what could be in some cases an unnecessarily restrictive approach to constraining that variability" (emphasis added). Application of this concept of a longer term average is appropriate in this case due to significant variability of boiler emissions due to a variety of factors including (1) shifting of load from gas boilers or scrubbed boilers (30 and 31) to uncontrolled coal boilers during planned and unplanned outages and (2) changes in plant steam load demand caused by seasonal factors as well as market demands and planned and unplanned manufacturing process outages. Additionally, two of the sources (boilers 30 and 31) included in this modeling study are equipped and are operated with SO_2 emissions control devices that can have very short-term elevated emissions during boiler startups and malfunctions (e.g. lime slurry feed system malfunctions). For such sources seeking alternate or longer-term emission limits, EPA's guidance notes that:

> "Sources with emission control equipment may be especially prone to periodic occurrences of high emissions, arising on occasions when the control equipment is not operating or operating at reduced efficiency. Therefore, the EPA finds it advisable that longer-term average limits for sources that meet these limits through the use of emission control equipment be subject to supplemental limits that serve to constrain the frequency and/or magnitude of occasions of elevated emissions. Establishment of such supplemental limits as part of a longer-term averaging approach is especially important in cases with significant potential for frequent and/or high magnitude occasions of elevated emissions, including, but not limited to, sources using emissions control equipment."

Discussions for the proposed SO_2 emission limits for each station are presented in the next four sub-sections.

Appendix C of the EPA's guidance provides an example in which a permitted rolling 30-day emission rate is related to the ratio of a high percentile 30-day emission rate divided by a high percentile 1-hour emission rate. In its example, EPA uses a 99th percentile, likely due to the assumption that for 1% of the time, the higher emission rates would not matter because the form of the 1-hour SO_2 NAAQS is a 99th percentile statistic.

For the purposes of calculating a rolling 30-day average SO_2 emission limit, Eastman elected to follow the procedure included in EPA's nonattainment guidance document, Appendix C.

---

[33] http://www3.epa.gov/airquality/sulfurdioxide/pdfs/20140423guidance.pdf

Step 1: Determine the critical emission rates for 1-hour averages that would result in the 5-year average of the annual 99th percentile of daily maximum hourly SO_2 concentrations at the level of the NAAQS. This step was completed and documented in Section 6.2 of this report. The critical emission rates modeled for each stack are shown in Table 6-2.

These emissions form the basis for a three-stack combined emission limit using 30-day to 1-hour ratios, as described below using EPA's procedures noted below from the Appendix C guidance and following the Hillsborough County, Florida example.

Step 2: Compile hourly emissions data reflecting the distribution of emissions that is expected once the compliance plan is implemented. These distributions describe the frequency with which different emission levels occur. For Eastman, the emissions over the last 3 years of operation (2013-2015) are expected to be representative of future year operations.

Step 3: Use the distribution of hourly emissions data obtained in Step 2 to compute a corresponding distribution of longer-term (30-day) emission averages.

Step 4: Use the distributions of the hourly values compiled in Step 2 and the longer-term average values computed in Step 3. This step determines the 99th percentile of the 1-hour average emission values compiled in Step 2 and the 99th percentile of the longer-term average emission values computed in Step 3.

Step 5: Compute the ratio of the two 99th percentile values from Step 4. For Eastman, this ratio is 0.92. A spreadsheet with the calculation is provided in the modeling archive.

Step 6: Multiply this ratio times the critical emission (1-hour) value to obtain the longer-term emission limit, which may be considered to have comparable stringency as a 1-hour limit at the modeled attainment level. For Eastman, the equivalent 30-day average emission limit is as follows:

- For the three stacks combined, 1,905 x 0.92 = 1,752 lb/hr.[34]

Because of the voluminous amount of data used in support of these calculations, these data are not included in this report, but are rather included with the modeling files forwarded to TDEC.

[34] Since all the 30-day limits computed and shown in Tables 5-2 and 5-4 are the same (1752 lb/hr), there is no need for stack-specific limits with the exception of the stack serving Boilers 30 and 31. The derived 30-day limit for that stack is 1656 lb/hr, but it is noted the Title V permit for these units sets lower limits (317 lb/hr, the 30-day rolling average) for Boiler 30 and 293 lb/hr (30 day rolling) for Boiler 31, for a total of 610 lb/hr for the 30-day rolling average. It is evident from the modeling results that the Title V SO_2 emission limit for Boilers 30 and 31 is protective of the SO_2 NAAQS.

Appendix A: Exhaust Parameters Determination

This appendix describes procedures that were used to develop relationships for computing exhaust temperature and velocity as a function of emissions for stacks serving boilers 18-22, 23-24, and 30-31.

Hourly SO_2 emissions, exhaust temperature and flow for each stack for the field study year (April 1, 2012 - March 31, 2013), which is representative of current boiler conditions, were provided by TDEC to AECOM and Eastman. TDEC had developed exhaust temperature and velocity for a specific set of emissions. However, due to the need to model other emission cases AECOM needed to generalize the relationships between emission rate and temperature or exit velocity to all emission rates. To do this, we used the TDEC's set of specific emissions and exhaust parameters (a set of 3-5 data points were provided), plotted them, and developed best-fit equations for those data points.

Table A-1 shows exhaust parameters for specific emission cases as developed by TDEC. AECOM has plotted the five data points, shown in Figure A-1 and A-2 for the boilers 23-24 and in Figures A-3 and A-4 for the boilers 23-24. A second order polynomial trend line was the best fit for the velocity data points and a linear trend line was the best fit for the temperature data points. The figures display the resulting equations produced by Excel.

Due to emissions control and base loading, boilers 30-31 velocity and temperature have relatively little variation with emissions. Therefore, only three data points were sufficient to depict the relationship between the emissions and exhaust parameters. Figure A-5 and A-6 shows these data points and the resulting linear fit equations.

Velocity and temperature for boilers 18-22, 23-24, and 30-31 for the purposes of load analyses and compliance modeling were computed as a function of emissions using the equations as described above and also summarized in Table A-2.

In addition to the equations, an upper limit on temperature and velocity was conservatively established for each stack, based upon actual data. These limits are also listed in Table A-1 and Table A-2. AECOM reviewed the year of the TDEC-provided data and found typical high load temperatures and velocities that were used as upper limit values.

Table A-1: Boilers 18-22 Emission Bins and Corresponding Velocities and Temperatures

Data Range Used (lb/hr)	Avg. SO_2 Emissions (lb/hr)	Avg. Stack Velocity (ft/s)	Avg. Stack Temperature (°F)	Number of data points

Appendix B: Population Estimate Using Facility Heat Release Data

AERMOD's Model Formulation for Urban Dispersion

In urban areas, AERMOD accounts for the dispersive nature of the "convective-like" boundary layer that forms during nighttime conditions by enhancing the turbulence over that which is expected in the adjacent rural, stable boundary layer. The enhanced turbulence is the result of the urban heat flux and associated mixed layer, which are estimated from the urban-rural temperature difference as suggested by Oke (1978; 1982)[35,36].

Although urban surface characteristics (roughness, albedo, etc.) influence the boundary layer parameters at all times, the effects of the urban sublayer on the structure of the boundary layer is largest at night and relatively absent during the day (Oke,1998)[37]. An urban "convective-like" boundary layer forms during nighttime hours when stable rural air flows onto a warmer urban surface. Following sunset, the urban surface cools at a slower rate than the rural surface because buildings in the urban area trap the outgoing thermal radiation and the urban subsurface has a larger thermal capacity. AERMOD accounts for this by enhancing the turbulence above that found in the rural stable boundary layer (i.e., a convective-like urban contribution to the total turbulence in the urban stable boundary layer). The convective contribution is a function of the convective velocity scale, which in turn, depends on the surface heat flux and the urban mixed layer height. The upward heat flux is a function of the urban-rural temperature difference, where the urban temperature is taken at the core of the urban area.

The urban-rural temperature difference depends on a large number of factors that cannot easily be included in applied models such as AERMOD. For simplicity, the data presented in Oke (1973; 1982)[38,2] is used to construct an empirical model. Oke presented observed urban-rural temperature differences for a number of Canadian cities with populations varying from about 1000 up to 2,000,000. These data represent the maximum urban effect for each city since they were collected during ideal conditions of clear skies, low winds, and low humidities. An empirical fit to the data yields the following relationship:

$$\Delta T_{u-r} = \Delta T_{max} [0.1 \ln (P/Po) + 1.0] \quad (1)$$

where $\Delta T_{max} = 12°C$, $Po = 2{,}000{,}000$ (the city population associated with the maximum temperature difference in Oke's data), and P is the population of the urban area being modeled. Since the ambient nighttime temperature of an urban area is higher than its surrounding rural area, an upward surface heat flux must exist in the urban area. It is assumed that this upward surface heat flux, Hu, is related to the urban-rural temperature difference through the following relationship

$$H_u = \alpha \rho c_p \Delta T_{u-r} u_*, \quad (2)$$

where Hu is the anthropogenic ("excess") heat release in units of watts per square meter in the "urban core" (an industrial area at least a few hundred meters on a side[39]).

[38] Oke, T. R., 1973. City size and the urban heat island. Atm.Env., 7: 769-779.

[39] In a series of personal communications, Dr. Steve Hanna indicated that the minimum size of an industrial area needed to take on "urban" characteristics has been the subject of much discussion over the years. He indicated that

As noted in the AERMOD formulation document[40], α is an empirical constant (0.03), ρ is the density of air (about 1.2 kg/m^3), c_p is the specific heat at constant pressure (1 watt-sec/g-deg K), and, as noted above, u_* is on the order of 0.1 m/s. This Equation 2 can be solved for ΔTu-r:

$$\Delta Tu\text{-}r \sim Hu/4, \quad (3)$$

where Hu is in units of watts per square meter and the temperature difference is in deg K.

Effective Population Estimate for Eastman Facility

Satellite Data Approach to Determine Urban-Rural Temperature Difference

Thermal satellite data over the Eastman Facility and surrounding area was used to determine urban-rural temperature difference ($\Delta T_{u\text{-}r}$) and then solve Equation 1 to determine effective population. The procedures for conducting this estimate are described in a white paper[41], in a peer-reviewed paper[42], and are also discussed in the open literature (e.g., Fung et al., 2009[43] and Nichol, 2005[44]). From Equation 1, the effective population, P, is expressed as:

$$P = Po \exp [10(\Delta T_{u\text{-}r} / \Delta T_{max} - 1.0)], \quad (4)$$

where

ΔT_{max} = 12 degrees

Po = 2,000,000.

A thermal satellite surface brightness temperature from ASTER Band 14 (April 1, 2010, 11 LST) shown in Figure B-1 indicates that the $\Delta T_{u\text{-}r}$ at the facility is roughly 9 degrees above the surrounding rural area. Using Equation 2, this temperature increase resulted in an effective population of about 200,000.

---

an "expert elicitation" would likely result in a minimum size estimate of a few hundred meters. The anthropogenic heat release per unit area of major cities such as Indianapolis (extensively studied by EPRI in the 1980s) would be on the order of 50 watts/m^2.

Engineering Estimates Approach to Determine Urban-Rural Temperature Difference

Figure B-2 engineering estimates of the total heat release from the facility and is equal to about 2100 MMBtu/hr, or about 600 MW. If approximately 50% of this is assumed to escape to the atmosphere (vs. being absorbed by ground, buildings, etc.), then this is equivalent to about 300 MW. The area occupied by the Eastman Facility is about 8 km^2. Then the anthropogenic heat release (Hu) in units of watts per square meter amounts to 37.5 W/m^2. Solving Equation 3, urban-rural temperature difference (ΔT_{u-r}) is about 9 deg K (or 15 deg F). Then, using Equation 4, the resulting effective population is about 200,000.

1.0 Introduction

1.1 Background

The additional TDEC updated modeling analysis supplements the modeling methodologies and procedures as described in Attachment H1a. This analysis addresses a two-stack scenario, one stack represents Boilers 18-24 (Stack C for the B-83 powerhouse was removed from service September 2021) and another stack for Boilers 30-31 (B-325 powerhouse).

1.2 Organization of Report

Section 2 describes the revised meteorological data. Section 3 addresses the updated background concentrations. Section 4 details the load analysis and the TDEC additional 12 modeling scenarios for the critical emission value (CEV) runs.

Application of the modeling approach to determine the CEV, the use of the SO_2 emission distributions for the stacks associated with boilers 18-24 and 30-31 to determine a rolling 30-day emission limit applicable to the total emissions of these two stacks is discussed in Section 5.

2.0 Site-specific Meteorological Data Processing

(This topic is also addressed in Section 7.4 of the SIP narrative).

In the 2017 AD submittal, Eastman onsite meteorological data used the 1992 NLCD and applied the adjustment to the horizontal friction velocity (ADJ_U*) and without the application of turbulence (sigma-theta and sigma-w) turbulence parameters in the Eastman SO2 modeling.

In the Summer of 2020, EPA has indicated concerns over the use of (ADJ_U*) Beta option and turbulence issues, so the onsite met data was revised to remove the adjustment to the horizontal friction velocity and keeping the application of turbulence.

Subsequently, in August of 2020, EPA has indicated concerns over the inclusion of turbulence measurements at all in the onsite meteorological data when using the urban dispersion option with the associated heat island effect because of the double counting of the turbulence effect from the measurements and the urban option based on the 2018 and 2021 EPA's AERMOD implementation guidance[1], which indicates that sigma-theta and/or sigma-w should not be used when running AERMOD in urban mode as stated below in Section 3.3 of the guidance:

"The use of site-specific meteorological data obtained from an urban setting may require some special processing if the measurement site is located within the influence of the urban heat island and site-specific turbulence measurements are available (*e.g.*, σθ and/or σw). As discussed in Section 5.4, the urban algorithms in AERMOD are designed to enhance the turbulence levels relative to the nearby rural setting during nighttime stable conditions to account for the urban heat island effect. Since the site-specific turbulence measurements will reflect the enhanced turbulence associated with the heat island, site-specific turbulence measurements should not be used when applying AERMOD's urban option, in order to avoid double counting the effects of enhanced turbulence due to the urban heat island."

Accordingly, the 1992 NLCD onsite met data was revised by the removal of the ADJ_U* in the

1 AERMOD Implementation Guide, EPA-454/B-21-006, July 2021. Sigma-theta is the standard deviation of the horizontal wind direction fluctuations. Sigma-w is the standard deviation of the vertical wind speed fluctuations.

AERMET surface met data file and by also removing the measured turbulence during stable conditions (i.e., nighttime) by assigning missing values for sigma-theta and sigma-w in the AERMET profile met data file.

Finally, in September 2022, and in response to the EPA R4 comments regarding the 2/2022 draft AD submittal, TDEC has updated the Eastman onsite met with the 2011 NLCD and with the application of the latest version of AERMET (version 22112). This final meteorological set consists of using the 2011 NLCD and the removal of the adjustment to the horizontal friction velocity (ADJ_U*) and the removal of turbulence (by assigning sigma-theta and sigma-w missing values) during stable hours only, which is processed through AERMOD (NOTURBST) as it is now an available option with the latest version of AERMOD (version 22112).

---

[1]AERMOD Implementation Guide, EPA-454/B-21-006, July 2021.
Sigma-theta is the standard deviation of the horizontal wind direction fluctuations.
Sigma-w is the standard deviation of the vertical wind speed fluctuations.

3.0 Regional Source Inventory

To account for the impact of sources other than Eastman, it is necessary to include the contributions of any identified nearby SO_2 sources as well as distant sources that would have a relatively uniform (regional) concentration impact over the non-attainment area. The regional sources included in the updated modeling (dated 2023-0120) are the Domtar Paper company and the Cardinal Glass facility with its updated SO_2 emissions (Section 3.2 of the SIP narrative).

Tennessee identified other large sources of SO_2 emissions within 50 kilometers of the nonattainment area as follows:

Tennessee Facilities: Title V facilities in Sullivan (excluding Eastman Chemical Company, Domtar, and Primester), Hawkins, Greene, Washington, Unicoi, Carter, and Johnson Counties are shown in **Table H9-1**. Tennessee reviewed all allowable SO_2 emissions above 100 tons/year and determined that only one facility (Cardinal Flat Glass) had the potential to contribute to a violation of the SO_2 NAAQS and therefore was included in the updated modeling for the n12 CEV runs (dated 2023-0120). The highest contribution to the design value from this facility is 0.2 ppb (Run 2023-0120-7), which is insignificant.

Virginia Facilities: Tennessee contacted the Virginia Department of Environmental Quality (DEQ) and asked Virginia to identify any large SO_2 sources (> 100 tons/year within the past five years) in Lee, Scott, Wise, Dickenson, Washington, or Russell Counties. Based on the information provided by Virginia, Tennessee identified two additional facilities for additional review (**Table H9-2**).

All the remaining sources will be screened out from the modeling based on the 20D magnitude approach of Q/D (Annual Emissions in tons-per-year over Distance in km), where the Q/D ratio is less than 20 denoting an insignificant source, which can be screened out from the modeling. This screening method is referenced from North Carolina DNR screening procedure threshold for PSD applications dated July 22, 1985.

Q/D Calculations: For the three facilities with greater than 100 tons/year of SO_2 emissions, Tennessee calculated the difference between each facility and the nonattainment area based on latitude/longitude data. Tennessee calculated Q/D for each facility using the 2020 emissions inventory for Cardinal Flat Glass and the highest reported SO_2 emissions from the last five years for the Virginia facilities (**Table H9-3**).

Geography: Tennessee reviewed the geography surrounding each facility using the terrain function of Google Maps. Tennessee also consulted with Virginia DEQ to assess the geography of the two Virginia facilities. Maps showing the location of each facility and prominent terrain features are shown in **Figures H9-1, H9-2, and H9-3.**

Table H9-3: Q/D Calculations					
Facility	**Latitude**	**Longitude**	**Distance from Nonattainment Area (km)**	**SO_2 Emissions (tons/year)**	**Q/D**
Cardinal Flat Glass	36.499521	-82.779694	23	421.58	18.33
American Electric Power-Clinch River Plant	36.933401	-82.199203	55	174	3.16
Dominion Energy – Virginia City Hybrid Energy Center	36.91645	-82.33816	48	119	2.48
All calculations are based on a nonattainment area reference point centered on the B-83 powerhouse stacks (36.519802° latitude and -82.539094° longitude)					

Figure H9-1: Map of Cardinal Flat Glass Relative to Kingsport, Tennessee

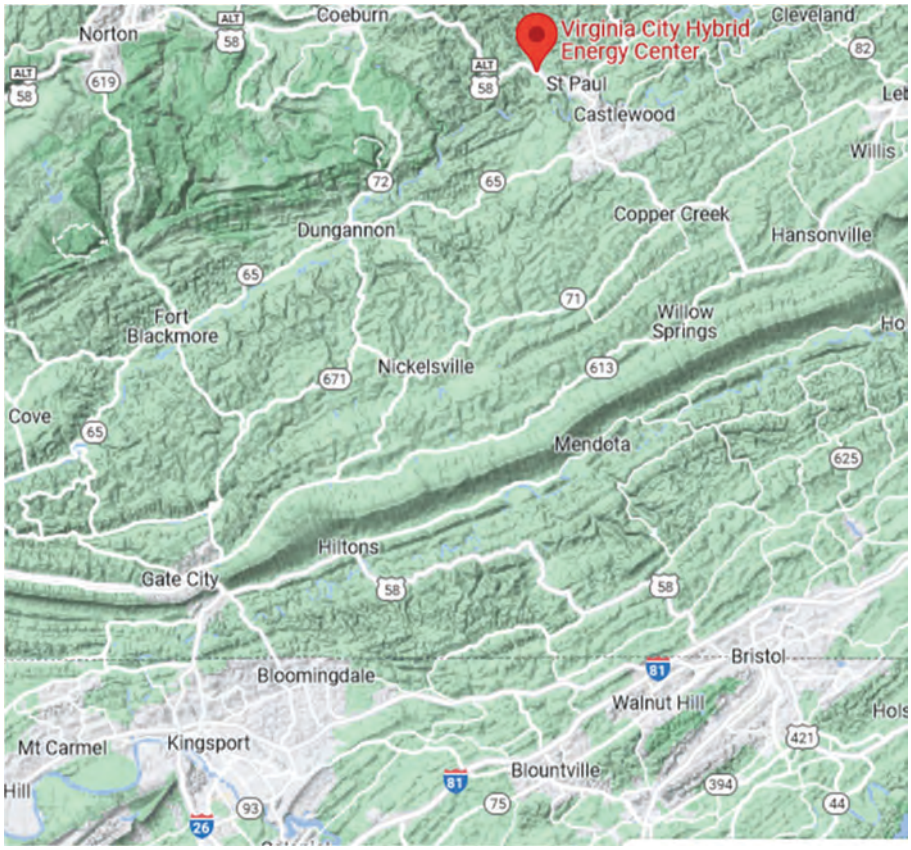

Figure H9-2: Map of Virginia City Hybrid Energy Center Relative to Kingsport, Tennessee

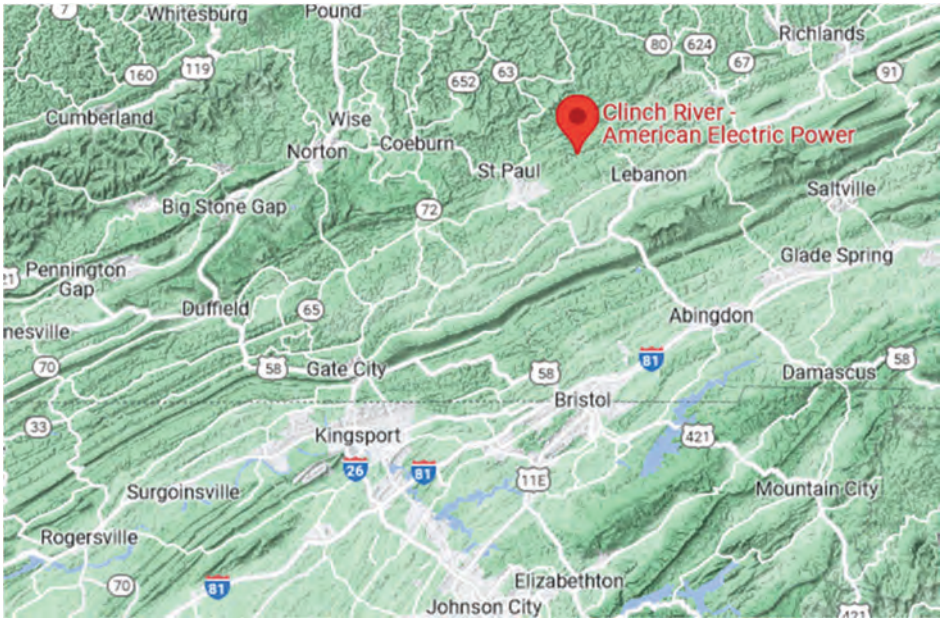

Figure H9-3: Map of American Electric Power Clinch River Plant Relative to Kingsport, Tennessee

Cardinal Flat Glass: Of the three facilities assessed, Cardinal Flat Glass is least impacted by the surrounding geography. Cardinal Flat Glass is located in the Holston River valley in Hawkins County and is upwind of the nonattaining monitor. The most prominent terrain feature in this area is Bays Mountain, which runs southwest to northeast through Sullivan and Hawkins Counties. Bays Mountain is approximately 2,000 feet above sea level and about 800 feet higher than the surrounding valley (the nonattaining monitor and Cardinal Flat Glass are both located at approximately 1,200 feet above sea level). Bays Mountain terminates near Kingsport, near the confluence of the North and South Forks of the Holston River. Bays Mountain does not block the transport of emissions from the facility to the nonattainment area, but since the facility and the nonattainment areas are located on opposite sides of

the mountain, the geography of the area may inhibit transport. This facility (representing two melting furnaces) was included in the updated modeling (dated 2023-0120).

Virginia City Hybrid Energy Center: The prominent terrain feature relative to this facility is Clinch Mountain, which runs southwest to northeast through Hawkins and Hancock Counties in Tennessee and Scott and Russell Counties in Virginia at an elevation of 2,000 to 2,500 feet above sea level. The mountain is unbroken save for a single gap between Weber City and Gate City in Virginia. This facility is located in St. Paul, Virginia, at an elevation of approximately 1,500 feet, and the nonattainment area lies on the opposite side of the mountain at a similar elevation (approximately 1,200 feet). Virginia DEQ also noted2 that the nonattaining monitor is upwind of the Virginia City Hybrid Energy Center, and emissions from the facility would be transported away from Sullivan County.

American Electric Power Clinch River Plant: American Electric Power's Clinch River Plant is located on the opposite side of Clinch Mountain from Kingsport. The Clinch River Plant is located on the Clinch River (approximately 1,500 feet above sea level) northeast of Kingsport, east of St. Paul, Virginia, and northwest of Lebanon, Virginia. The terrain is sharper in the vicinity of this facility, and Clinch Mountain rises to approximately 4,000 feet above sea level near Lebanon. Virginia DEQ assessed this facility3 and found that the Clinch River Plant's emissions, alone or as an interaction with cross-state emissions, are unlikely to cause or contribute to a violation of the 2010 SO_2 NAAQS in a neighboring state. Tennessee notes that this facility is generally upwind of Kingsport, and emissions would tend to be transported away from the nonattainment area.

2 *Commonwealth of Virginia §110(a)(2)(D)(I) Good Neighbor Provisions*, 2010 SO_2 NAAQS, draft document transmitted to Tennessee June 2022.
3 *Ibid*.

4.0 SO2 Ambient Background Concentrations

(This topic is also addressed in Section 7.5 of the SIP narrative).

To account for regional background concentrations, recent guidance provided by EPA has suggested the use of ambient SO_2 concentrations from the monitor located at Mammoth Cave National Park in Kentucky (AQS ID 21-061-0501). TDEC calculated and updated the most recent 3 years (2019-2021) of the hourly varying "season-by-hours-of-day" background dataset using procedures described in the March 1, 2011, EPA guidance [2]. The seasonal by hour of the day ambient background value was processed within the model using the BACKGRND SEASHR keyword in the source card.

Table H9-4: 2019-2021 Background Concentrations (ppb) from MMCA for Each Season by Hour of Day

Hour	Winter	Spring	Summer	Fall
1	1.13	0.80	0.57	0.97
2	1.15	0.80	0.55	0.95
3	1.15	0.70	0.70	1.20
4	1.35	0.65	0.65	0.60
5	1.65	0.70	0.55	0.55

24	1.20	0.80	0.40	1.35

[2] This guidance is available at https://www.epa.gov/sites/default/files/2015-07/documents/appwno2_2.pdf

5.0 Determination of Long-Term SO_2 Permit Emission Limits

The "critical emission value" for a facility is the maximum 1-hour average emission rate that, when combined with background, results in a design concentration that just complies with the NAAQS. The critical value is used as a reference point for setting a longer-term emission rate. This section describes a load analysis, critical emission values modeling approach, and the resulting long-term SO_2 permit limit for the Eastman Facility.

5.1 Load Analysis

The AERMOD modeling analysis was conducted with emission rates and exhaust characteristics (velocity and temperature) that represent a range of possible values for the Eastman 83 Powerhouse boilers 18-24 and for 325 Powerhouse boilers 30-31 during steady-state operations.

Tennessee determined a range of operational cases to model at a maximum emission rate (combined total for both stacks) of 1,600 lb/hr. Future SO_2 emissions for B-83 and B-325 were based on hourly SO_2 emission rates occurring between July 1, 2019, and December 31, 2020 (Attachment E). Tennessee considers these data to be representative of facility operations based on the amount of data and the range of operating conditions addressed by the dataset (e. g., periods with high and low heat inputs, maintenance outages, etc.).

The modeling input parameters and results of the load analysis are listed in Table 4-2. As expected, the worst- case load cases were the high load case for each stack.

5.2 Critical Emission Value Modeling Approach

The critical emission value (CEV) is the short-term (1-hour average in this case) constant emission rate that results in a design concentration at or below the NAAQS. Based upon EPA's SO2 nonattainment modeling guidance[3], the critical value can be used as a reference point for setting a longer-term emission rate. For the critical value runs, the temperature and velocities for the 83 and 325 sources were determined using equations from Attachment H3.

The CEV air dispersion modeling evaluation was performed using EPA's preferred air dispersion model AERMOD (version 21112). The one-stack and two-stack emissions scenarios were evaluated for a 1600 lb/hr limit for the coal-fired Boilers 18-24 and Boilers 30-31 in addition to all sources from Eastman and the Domtar Paper nearby source. Results of the modeling analysis for the different emission scenarios are shown in Table 4-3.

With two different stacks, many different possible combinations of critical values are possible for resulting in a design concentration at or below the NAAQS. In addition, the facility load can shift among the 18-24 and 30-31 units so that they would not be emitting at peak rates simultaneously.

---

[3] EPA, April 23, 2014. Guidance for 1-hour SO2 Nonattainment Area SIP Submissions, available at https://www.epa.gov/sites/production/files/2016-06/documents/20140423guidance_nonattainment_sip.pdf.

However, for the worst-case impact, Case 1, all the load was shifted to the 83 boilers source. These additional 12 cases were expanded to make sure the emissions for one and two-stack scenarios will comply with the NAAQS, as these emissions scenarios are shown in Table 4-1 (with stack parameters listed in Table 4-2), to show NAAQS compliance over all the cases modeled as shown in Table 4-3.

All 12 cases show modeled SO_2 NAAQS attainment (concentrations not exceeding 196.5 $\mu g/m^3$).

The modeled sources and their emission rates for the highest impact (case 1) are shown in Table 4-4. Concentration isopleths for this run are shown in Figure 4-1 and the location of the modeled highest-4^{th} -high impact is shown in Figure 4-2.

The modeled sources and their emission rates for the highest impact for a two-stack scenario (case 9) are shown in Table 4-5. Concentration isopleths for this run is shown in Figure 4-3 and the location of the modeled highest-4^{th} -high impact is shown in Figure 4-4.

Table H9-5: Basis of Emission Rates for (1-Stack and 2-Stack) Modeled Cases

Run	Number of Stacks	Boiler(s)	Total SO_2 Emissions (lb/hr)	
2021-1129-1	1	18, 19, 20, 21, 22	1600.0	18-22 at max emission rates, 23-24 down, 30-31 down. Basis for stack parameters is 2/15/21 runs adjusted from 1615 lb/hr to 1600 lb/hr
2021-1129-2	2	18, 19, 20, 21, 22, 23, 24, 31	1600.0	Boiler 30 down, Boiler 31 at 95th percentile, Boilers 18, 19, and 22 at 98th, Boilers 20, 21, 23, and 24 at 95th percentile
2021-1129-3	2	20, 21, 22, 23, 24, 30	1600.0	Boiler 31 down, Boiler 30 at 95th percentile, Boilers 18-22 at 95th or 98th percentiles
2021-1129-4	2	19, 21, 22, 23, 24, 31	1600.0	Boiler 30 down, used updated 98th percentile stack parameters for Boiler 31
2021-1129-5	2	20, 21, 22, 23, 24, 30	1600.0	Boiler 31 down, used updated 98th percentile stack parameters for Boiler 30
2021-1129-6	2	20, 21, 22, 23, 24, 30	1600.0	Boiler 31 down, Boiler 30 at adjusted 30-day allowable, Boilers 20, 21, 22, 23, and 24 at 95th percentile
2021-1129-7	2	21, 22, 23, 24, 31	1600.0	Boiler 30 down, Boiler 31 at adjusted 30-day allowable, Boilers 21, 22, 23, and 24 at 95th percentile
2021-1129-8	2	22, 23, 24, 30, 31	1600.0	Adjusted B-325 downward to 1,600 lb/hr total. Used updated 98th pc stack parameters for 30 & 31
2021-1129-9	2	18, 19, 20, 21, 22, 30, 31	1600.0	Adjusted B-325 downward to 1,600 lb/hr total. Used updated 98th pc stack parameters for 30 & 31
2021-1129-10	2	23, 24, 30, 31	1516.0	For 23 & 24, used 5-year max. pre-control emission rate and permanent DSI estimated efficiency (60% control), 30-31 at adjusted 30-day allowable
2021-1129-11	2	19, 23, 24, 30, 31	1600.0	30 & 31 at max. (NSPS allowable divided by compliance ratio). Used updated 98th pc stack parameters for 30 & 31
2021-1129-12	2	18, 19, 20, 21, 22, 30, 31	1600.0	30 & 31 at max. (NSPS allowable divided by compliance ratio). Used updated 98th pc stack parameters for 30 & 31

Figure H9-8: H4H Concentration Isopleths for Case 9

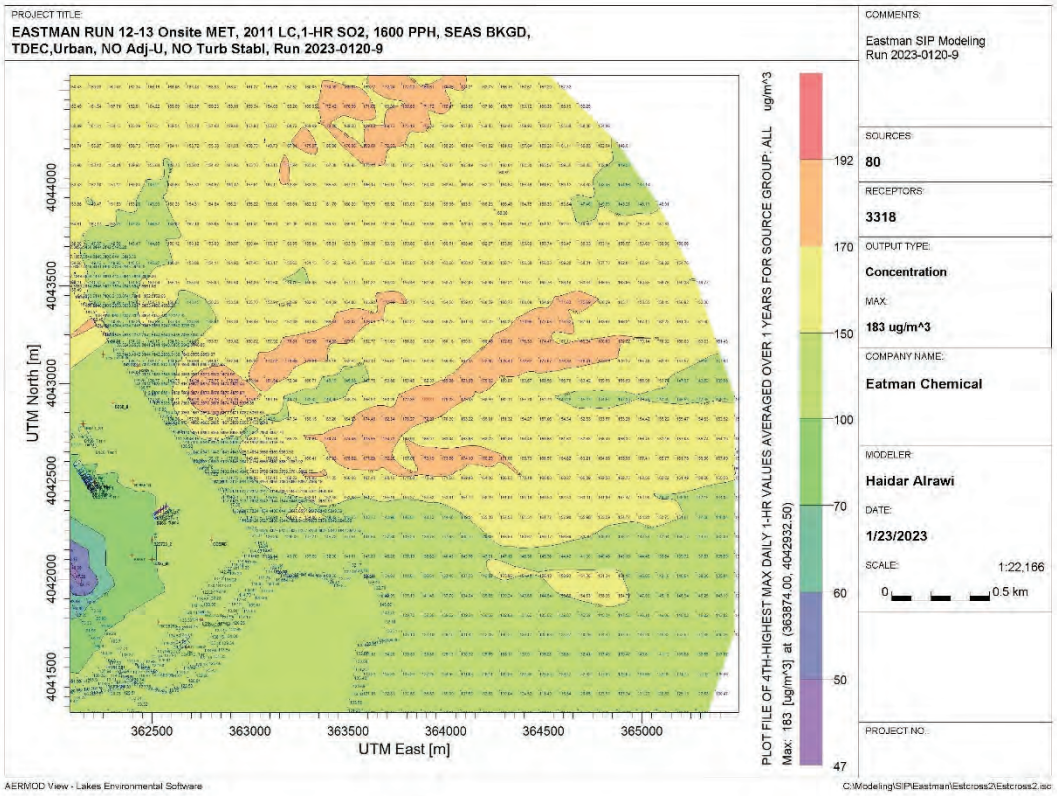

Figure H9-9: H4H Max Concentration Impact for Case 9

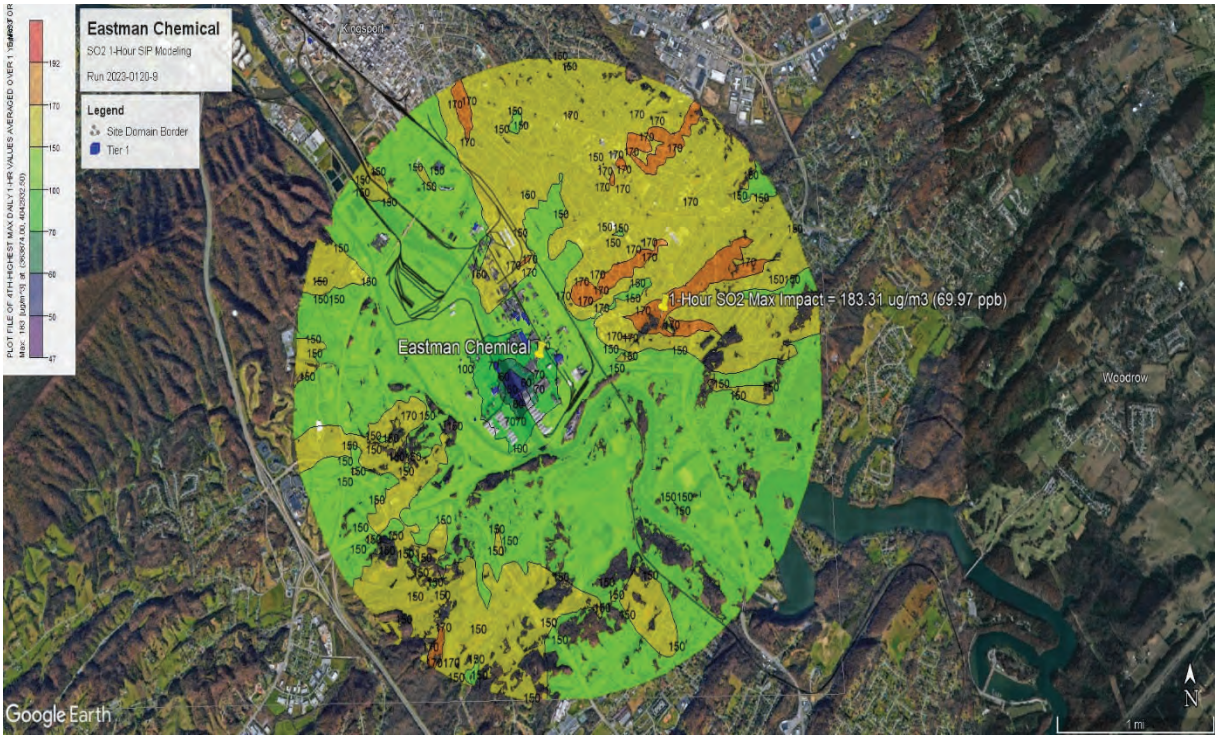


6.0 Determination of the Appropriate Long-term Average Emission Rates for Permit

EPA's April 23, 2014, guidance[5] for resolving SO_2 nonattainment areas acknowledges "that it may be possible in specific cases for states to develop control strategies that account for variability in 1-hour emissions rates through emission limits with averaging times that are longer than 1 hour, using averaging times as long as 30-days, but still provide for attainment of the 2010 SO_2 NAAQS." EPA's general expectation is that for infrequent periods of hourly emissions above the critical emission value, "these periods would be unlikely to have a significant impact on air quality, insofar as they would be very unlikely to occur repeatedly at the times when the meteorology is conducive for high ambient concentrations of SO_2. EPA considers this option to be an "appropriate balance between providing a strong assurance that the NAAQS will be attained and maintained, while still acknowledging the necessary variability in source operations and the impairment to source operations that would occur under what could be in some cases an unnecessarily restrictive approach to constraining that variability" (emphasis added). Application of this concept of a longer-term average is appropriate in this case due to significant variability of boiler emissions due to a variety of factors including (1) shifting of load from gas boilers or scrubbed boilers (30 and 31) to uncontrolled coal boilers during planned and unplanned outages and (2) changes in plant steam load demand caused by seasonal factors as well as market demands and planned and unplanned manufacturing process outages. Additionally, two of the sources (boilers 30 and 31) included in this modeling study are equipped and are operated with SO_2 emissions control devices that can have very short-term elevated emissions during boiler startups and malfunctions (e.g., lime slurry feed system malfunctions). For such sources seeking alternate or longer-term emission limits, EPA's guidance notes that:

> "Sources with emission control equipment may be especially prone to periodic occurrences of high emissions, arising on occasions when the control equipment is not operating or operating at reduced efficiency. Therefore, the EPA finds it advisable that longer-term average limits for sources that meet these limits through the use of emission control equipment be subject to supplemental limits that serve to constrain the frequency and/or magnitude of occasions of elevated emissions. Establishment of such supplemental limits as part of a longer-term averaging approach is especially important in cases with significant potential for frequent and/or high magnitude occasions of elevated emissions, including, but not limited to, sources using emissions control equipment."

Appendix C of the EPA's guidance provides an example in which a permitted rolling 30-day emission rate is related to the ratio of a high percentile 30-day emission rate divided by a high percentile 1-hour emission rate. In its example, EPA uses a 99th percentile, likely due to the assumption that for 1% of the time, the higher emission rates would not matter because the form of the 1-hour SO_2 NAAQS is a 99th percentile statistic.

For the purposes of calculating a rolling 30-day average SO_2 emission limit, Eastman elected to follow the procedure included in EPA's nonattainment guidance document, Appendix C.

---

[5] https://www.epa.gov/sites/default/files/2016-06/documents/20140423guidance_nonattainment_sip.pdf

Step 1: Determine the critical emission rates for 1-hour averages that would result in the 5-year average of the annual 99th percentile of daily maximum hourly SO_2 concentrations at the level of the NAAQS. This step was completed and the **CEV is 1600.0 lb/hr**. The critical emission rates modeled for each stack are shown in Table 4-3.

These emissions form the basis for a two-stack combined emission limit using 30-day to 1-hour ratios, as described below using EPA's procedures noted below from the Appendix C guidance.

Step 2: Compile hourly emissions data reflecting the distribution of emissions that is expected once the compliance plan is implemented. These distributions describe the frequency with which different emission levels occur. For Eastman, the emissions over the 1.5 years of operation (7/1/2019-12/31/2020) are expected to be representative of future year operations.

Step 3: Use the distribution of hourly emissions data obtained in Step 2 to compute a corresponding distribution of longer-term (30-day) emission averages

Step 4: Use the distributions of the hourly values compiled in Step 2 and the longer-term average values computed in Step 3. This step determines the 99th percentile of the 1-hour average emission values compiled in Step 2 and the 99th percentile of the longer-term average emission values computed in Step 3.

The calculated **99th hourly emission value is 1252 lb/hr**. The calculated **99th emissions rate (30-day rolling average**) for all boilers is **976 lb/hr**.

Step 5: Compute the ratio of the two 99th percentile values (i.e., compliance ratio) from Step 4. For Eastman, **this ratio (976/1252**) **is 0.78**. A spreadsheet with the calculation is provided in the modeling archive.

Step 6: Multiply this ratio times the critical emission (1-hour) value to obtain the longer-term emission limit, which may be considered to have comparable stringency as a 1-hour limit at the modeled attainment level. For Eastman, the equivalent 30-day average emission limit is as follows:

- For the two stacks combined, **1,600 x 0.78 = 1,248 lb/hr**.

The results of the calculations are summarized in Table 5-1 below (and in Section 7.14 of the main narrative).

Table H9-11: Calculation of 30-Day Rolling Average Emission Limit	
Period of representative emissions	July 1, 2019, through December 31, 2020
99th percentile hourly emission rate (all boilers)	1,252 lb/hr
99th percentile 30-day rolling average emission rate (all boilers)	976 lb/hr
Compliance ratio	0.78
Modeled emission rate	1,600 lb/hr
Allowable emission rate	1,248 lb/hr, 30-day rolling average

Appendix – A

EPA Modeling Comments (dated 6/7/2022) and TDEC Response to the Comments

The U.S. Environmental Protection Agency's Preliminary Comments for the Tennessee Department of Environment and Conservation's (TDEC) Sulfur Dioxide (SO_2) Attainment State Implementation Plan (SIP) for Sullivan County, Tennessee

Key Comments:

1. **Section 7.8 - Selection of Sources to Model:** The draft SIP narrative provides information to support TDEC's determination that the cold and warm flares at the coal gasification plant operate intermittently and, therefore, were not included in the modeling for the attainment demonstration. TDEC references the discussion regarding treatment of intermittent emissions in the EPA's March 1, 2011, 1-hour NO_2 Modeling Guidance Memorandum (also referred to as the 2011 NO_2 Guidance Memo) as the basis for excluding the flares from the attainment modeling. The emission information in Tables 7-2 and 7-3 of the draft SIP narrative shows that SO_2 emissions rates from the flares are zero pounds per hour (lb/hr) for most of the time the flares have operated from 2017 through 2021, ranging from 94 percent to 99 percent of the operating hours; however, there are times when SO_2 emissions occur (e.g., up to 522 hours in 2018). Additionally, Figure 7-2 indicates that emission rates of hundreds of lb/hr, and as high as 5,000 lb/hr, occur infrequently.

   The EPA believes that the information in the draft SIP narrative does not conclusively demonstrate that the flare emissions are not "continuous enough or frequent enough to contribute significantly to the annual distribution of daily maximum 1-hour concentrations," which is the key criteria discussed in the 2011 NO_2 Guidance Memo. Therefore, the EPA requests Tennessee provide additional information to demonstrate that the emissions from the flares will not be frequent enough to impact the 99th percentile of the annual distribution of daily maximum 1-hour concentrations. This information should specifically address the frequency of the emissions "spikes," including a summary of the number of days per year with elevated SO_2 emissions rates. Alternatively, TDEC may consider alternative options for including the flares in the modeling demonstration, considering the relatively low frequency of their operation, such as modeling the emissions at a normalized annual rate as discussed in the 2011 NO_2 Guidance Memo. The EPA will continue to work with Tennessee to address this comment.

   TDEC Response to Comment 1:

   The Flare intermittent source (modeled emission point B351-5) was included in the updated modeling at an annualized SO2 emission rate of 6.25 lb/hr.

2. **Section 7.4 - Meteorological Data:** The discussion of the switch from using the ADJ_U* option to using the measured turbulence parameters is confusing. This section should be revised to clearly state that in the 2017 attainment demonstration, the modeling used the 2012-2013 site-specific meteorology with the ADJ_U* option applied in AERMET, and that the site-specific turbulence parameters (sigma-theta and sigma-w) were not used. This was changed in the 2022 attainment demonstration modeling, so that the site-specific turbulence parameters are being used during unstable atmospheric conditions (mainly daytime), but not during stable conditions (mainly nighttime), when the Urban option in AERMOD is being applied. This same comment applies to the discussion in the Modeling Report contained in Attachment H1b of the draft SIP narrative. Comment 15 identifies additional information related to the meteorological data that should be added to Section 2.0 of Attachment H1b.

TDEC Response to Comment 2:

The processing of the onsite meteorological data is updated and discussed in Section 7.4 of the main narrative and also in Section 2.0 of this document.

3. **Section 7.5 -Background Concentration:** The EPA requests that TDEC provide additional information in this section to justify use of ambient SO_2 concentrations measured at the Mammoth Cave background

monitor located in Kentucky. This section should discuss other potential ambient monitors that were considered for the background concentrations, including their location setting and distance from the Sullivan County nonattainment, compared to the location setting and distance of the Mammoth Cave monitor. Additionally, the details of the calculations of the "season by hour of day" values provided in Table 7-1 should be provided in an appendix (preferably in electronic form in a spreadsheet). This same comment applies to the discussion of background concentrations in section 3.0 of Attachment H1b.

TDEC Response to Comment 3:

The selection of the 2018-2020 representative SO2 ambient background concentrations is provided in Section 7.5 of the main narrative and also in Section 4.0 of this document. The details (spreadsheet) of the season-by-hour calculations are also provided in the electronic modeling archive.

4. **Attachment H1b, TDEC Supplemental CEV [Critical Emissions Value] Modeling Analysis, Section 1.1 Background:** The EPA recommends that this section also include a discussion of the other significant differences from the 2017 Attainment SIP modeling, including:

    a. The current modeling includes most of the SO_2 emissions sources at the Eastman facility modeled with their permit allowable emissions limits.
    b. The current modeling is being used to establish new CEVs and permit limits for the B-248 hazardous waste incinerator units.

TDEC Response to Comment 4:

This updated modeling analysis include all the 73 Eastman SO2 sources in addition to the Domtar Paper Company nearby source for a total of 74 modeled sources. All the sources (aside from the emissions variations CEV assessments for Boilers B-83 and B-325) were modeled at their PTE level or allowable emissions.

5. **Attachment H1b, TDEC Supplemental CEV Modeling Analysis, Section 1.2 Organization of Report:** A discussion of the building downwash analysis should be added to the report. This discussion should include details about how the BPIP pre-processor was used to calculate direction-specific building parameters and identify which emissions sources are included in the building downwash analysis.

TDEC Response to Comment 5:

The processing of the building downwash is addressed in Section 7.8 of the main narrative. There are 24 buildings/structures processed for 4 Stacks (Boilers B83-1822, B83-2324, B325 and B253) with the latest version of BPIP-PRM (version 04274). The building downwash data files are provided in the electronic modeling archive.

6. **Attachment H1b, TDEC Supplemental CEV Modeling Analysis, Section 2.0 Revised Meteorological Data Processing:** A much more detailed discussion of the revised meteorological data processing procedures is needed in this section that goes beyond the changes related to the use of ADJ_U* and on-site measured turbulence parameters. Attachment H1a contains the modeling report from the 2017 Attainment Demonstration. All changes that were made from the procedures discussed in Attachment H1a should be explained in this section. At a minimum, the following information should be addressed in this section:

    a. The version of AERMET used in the current modeling should be identified.
    b. Please clarify whether the cloud cover from the Bristol/Tri-cities National Weather Station (NWS) was used or was the Bulk Richardson Method used with on-site met data.
    c. Please clarify whether AERMINUTE was used when processing the Bristol NWS surface data that is being used to supplement the site-specific met data in AERMOD or was hourly ISHD data used.
    d. Include what version of AERSURFACE was used to process the surface characteristics.

Also include what version of NLCD data were used in AERSURFACE. Clarify if it was 1992 or something more recent.

e. All input and output meteorology data processing files for both AERMET and AERSURFACE should be provided for review.

TDEC Response to Comment 6:

Here are our responses to the listed items:

a. AERMET version 22112.
b. Cloud cover from the Bristol/Tri-City NWS was used.
c. AERMINUTE data used.
d. AERSURFACE version 20060 with 2011 NLCD.
e. All input and output files are provided in the modeling archive.

7. Attachment H1b, TDEC Supplemental CEV Modeling Analysis, Page. 2, Section 3.0: Any other large sources of SO2 emissions within 50 kilometers of the nonattainment area should be identified in this section and a rationale should be provided for not including them in the modeling.

TDEC Response to Comment 7:

The modeling assessment of regional sources located within 50Km of the Eastman Chemical facility is addressed in Section 2 of this document. All identified sources were excluded from modeling based on the Q/D (emissions over distance) analysis where their ratios are less than 20 (threshold). This methodology is based on the NC DNR screening assessment tool utilized for PSD applications in screening out sources from modeling (dated 7/22/1985).

Appendix – A – Continued

EPA Modeling Comments (dated 12/8/2022) and TDEC Response to the Comments

11. **Section 7.4, Meteorological Data:** The final paragraph of this section references use of 2011 National Land Cover Database (NLCD) data for calculating the surface characteristics input parameters used in AERMET. An explanation should be provided why 2011 NLCD data was chosen instead of the more recent 2016 NLCD data.

TDEC Response to Comment 11:

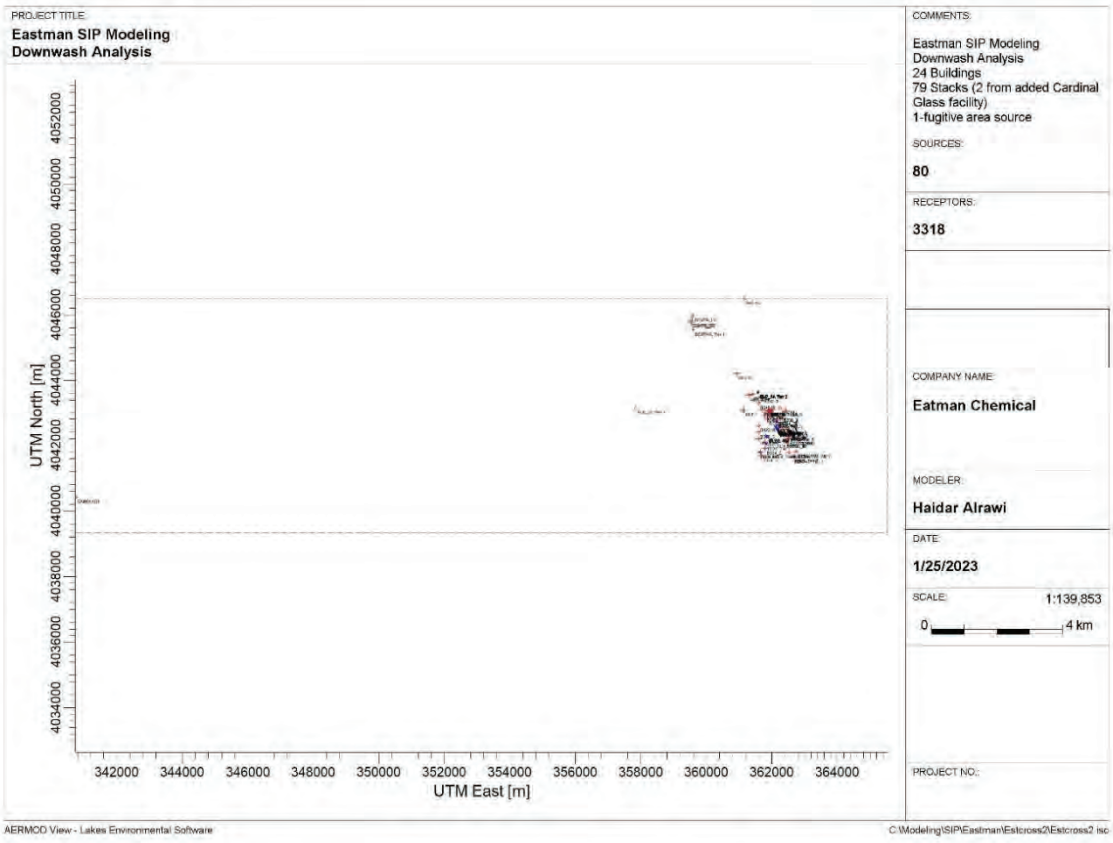
The quality of the 2016 NLCD data has been recently questioned in terms of it over-predicting modeled impacts. By examining the surface characteristics (for Albedo, Bowen Ratio and Surface Roughness) within 1-km surrounding the Eastman facility (centered on Powerhouse B-253 location) for the 1992, 2011 and 2016 NLCD as provided in the attachment (Eastman SC 1992-2011-2016 excel file), the average values of the critical surface roughness parameter are as follows: 0.439m (1992), 0.498m (2011) and 0.048m (2016). The 2016 value is reduced by almost an order of magnitude (90%) from the 2011 value, which is not actually representative of the actual topography of the Eastman facility within 1-km radius and the 2011 value is much closer to the 1992 value as the area has not changed much since that time and that is the basis of our selection of the 2011 data instead of the 2016 data.

12. **Section 7.8, Building Downwash Analysis:** The building downwash data and analysis summarized in Table 7-2 and Figure 7-3 appears to be incomplete. A review of the BPIP electronic modeling files included with the SIP submission indicates that all 77 point-sources included in the modeling were evaluated for building downwash. The discussion in this section should be revised to reflect the actual analysis performed in the final modeling**.**

TDEC Response to Comment 12:

TDEC has updated the downwash analysis by including two additional melting furnace stacks from the distant Cardinal Glass facility. So, there are a total of 24 Eastman buildings evaluated for downwash analysis from 79 point-sources stacks. The buildings and stack locations are shown below. Updated downwash data files will be provided with the final attainment demonstration.

Figure 1: Eastman Buildings Downwash



13. **Section 7.5.1, SO_2 Background Monitors:** Table 7-1 indicates that 2018–2020 data from the Mammoth Cave ambient monitor were used to calculate the season-by-hour background concentrations. An explanation should be provided why 2018–2020 data were used instead of the more recent 2019–2021 data that are currently available. If TDEC decides to revise the modeling runs based upon responses to other comments in this document, the EPA recommends using the more recent 2019–2021 data.

TDEC Response to Comment 13:

TDEC has revised and updated all the 12 CEV modeling runs using the most recent 2019-2021 data.

14. **Section 8.5, Emissions Sources Not Included in the SIP – Organic Acids & Anhydrides Manufacturing (MSOP-23), Table 8-39:** Table 8-39 provides data from Modeling Runs 2022- 0928-1R2 and 2022-0928-7R2. The electronic modeling files for Run 2022-0928-1R2 were not provided in the electronic modeling archive, so review of this run was not possible. Please provide the electronic modeling files for 2022-0928-1R2.

TDEC Response to Comment 14:

TDEC has revised and updated all the 12 CEV modeling runs as a clean slate so there should be no unique or specific revised runs (R2) modeling files. Updated model runs will be provided with the final attainment demonstration.

16. **Attachment H1b, Section 3.0, Regional Source Inventory:** This section indicates that all of the nearby sources discussed in this section were screened out of the modeling based upon the 20D approach of Q/D. The EPA does not endorse the use of the 20D approach for screening out sources for modeling to show attainment with the 2010 1-hour SO_2 NAAQS. For the majority of the sources listed in Tables H9-1 and H9-2, the EPA agrees that the information about the relatively low levels of emissions, large distances from the nonattainment area, and the topography influences demonstrate that these sources do not need to be explicitly modeled in the AERMOD modeling analysis, and their impacts are adequately accounted for with the background concentration. However, for the Cardinal Glass facility, the information presented does not clearly demonstrate that this source does not need to be explicitly modeled. The EPA recommends that additional information about the configuration of SO_2 emissions units (stack heights, velocities, temperatures, etc.) be provided to demonstrate that due to distance that the source does not have significant impacts in the nonattainment area. An additional option would be to perform screening modeling using AERSCREEN to make this demonstration.

TDEC Response to Comment 16:

The cardinal glass facility (two melting furnaces) was included in the updated modeling (dated 2023-0120) with its highest contribution to the design value been 0.2 ppb (Run 2023-0120-7), which is insignificant.

Attachment H2
Determination of Land Surface Temperature Using Landsat 8 TIRS Imaging, Kingsport, TN Area

Determination of Land Surface Temperature Using Landsat 8 TIRS Imaging Kingsport, TN Area

SUMMARY

BEAM-VISAT Version 5.0 software[1] was used in conjunction with methodology from *Quantifying Urban-Rural Temperature Differences for Industrial Complexes Using Thermal Satellite Data*[2] to quantify the difference in temperature between the Eastman Chemical Company facility and the surrounding area.

METHODOLOGY

The US Geological Survey provides the EarthExplorer tool, which allows users to access satellite imaging data from various satellite platforms and modules. For this evaluation, we used Landsat 8 thermal infrared radiation sensor (TIRS) data. The EarthExplorer web tool allows the user to filter images geographical area and data set (in this case, L8 OLI/TIRS), and then further select a scene based on cloud cover, time of day, etc. The scene selected for this analysis was a set of thermal images taken by the Landsat 8 OLI_TIRS module at April 26, 2013 at 4:07 PM (Landsat Scene ID LC80180352013116LGN01).

The scene data is provided in the form of radiance [$W/(m2 * steradians * \mu m)$] at the sensor. Multiple conversions and corrections are necessary to determine the temperature of the ground based on this radiance value. For this image processing, we used BEAM VISAT Version 5.0 and the split window algorithm (SWA) as explained in Appendix A of *Quantifying Urban-Rural Temperature Differences for Industrial Complexes Using Thermal Satellite Data*[3].

The processing of the data requires the radiance value presented by Bands 10 and 11 of the TIRS data to be transformed into band-specific at-satellite brightness temperature values, T_b, as described on the USGS Landsat guidance website[4]. This temperature is then converted to Celsius.

$$(1) \quad T_b = \frac{K_2}{ln\left(\frac{K_1}{L_\lambda}+1\right)} - 273.15$$

where,

T_b = At-satellite brightness temperature (C)

L_λ = TOA spectral radiance (Watts/(m^2 * srad * μm))

K_1, K_2 = Band-specific thermal conversion constants from the metadata

[1] http://www.brockmann-consult.de/cms/web/beam/

[2] Moore, Gary, et al. "Quantifying Urban-Rural Temperature Differences for Industrial Complexes Using Thermal Satellite Data." AECOM. April 2, 2014.

[3] Ibid.

[4] http://landsat.usgs.gov/Landsat8_Using_Product.php

Now that the brightness temperature has been determined for bands 10 and 11, the split window algorithm can be applied. The LandSat 8 split window algorithm (SWA) is presented in Rozenstein et al. (2014) and adapted by AECOM.

The standard mathematical model of the SWA for bands 10 and 11 is given by

$$(2) \quad T_S = A_0 + A_1 T_{10} - A_2 T_{11}$$

T_{10} and T_{11} are the brightness temperatures calculated from Eq. (1) for bands 10 and 11 respectively. Coefficients A_0, A_1, and A_2 are determined through a series of formulas (presented below) to account for the emissivity of the land surface cover and the transmissivity of the atmosphere.

Band	'a' coefficient	'b' coefficient
10	-62.8065	0.4338
11	-67.1728	0.4694

Coefficient	Formula
A_0	$E_1a_{10} + E_2a_{11}$
A_1	$1 + A + E_1b_{10}$
A_2	$A + E_2b_{11}$
A	D_{10}/E_0
E_0	$D_{11}C_{10} - D_{10}C_{11}$
E_1	$D_{11}(1 - C_{10} - D_{10})/E_0$
E_2	$D_{10}(1 - C_{11} - D_{11})/E_0$
D_{10}	$[(1 - \tau_{10})][1 + (1-\varepsilon_{10})\tau_{10}]$
D_{11}	$[(1 - \tau_{11})][1 + (1-\varepsilon_{11})\tau_{11}]$
C_{10}	$\varepsilon_{10}\tau_{10}$
C_{11}	$\varepsilon_{11}\tau_{11}$

Land surface emissivity, ε, requires computation of the normalized difference vegetation index (NVDI) in order to identify vegetation on the planetary surface in the TIRS image. The formula for NVDI is

$$(3) \quad NVDI = \frac{NIR - VIS}{NIR + VIS}$$

where VIS and NIR stand for the spectral reflectance measurements acquired in the visible red (band 4) and near-infrared (band 5) regions, respectively. Conversion of the radiance values provided by the LandSat 8 scene to reflectance is accomplished using the following equations, from the USGS Landsat guidance website[5].

$$(4) \quad Q_{cal} = \frac{L_\lambda - A_L}{M_L}$$

[5] Ibid.

$$(5) \quad \rho\lambda' = M_\rho Q_{cal} + A_\rho$$

where,

L_λ = TOA spectral radiance (Watts/(m2 * srad * μm))
M_L = Band-specific multiplicative radiance rescaling factor from the metadata
A_L = Band-specific additive radiance rescaling factor from the metadata
Q_{cal} = Quantized and calibrated standard product pixel values (DN)
ρλ' = TOA planetary reflectance, without correction for solar angle.
Mρ = Band-specific multiplicative reflectance rescaling factor from the metadata
Aρ = Band-specific additive reflectance rescaling factor from the metadata

Reflectance values were then corrected for sun angle via the equation

$$(6) \quad \rho\lambda = \frac{\rho\lambda'}{\cos\theta_{SZ}} = \frac{\rho\lambda'}{\sin\theta_{SE}}$$

where,

$\rho\lambda$ = TOA planetary reflectance, corrected
θ_{SE} = Local sun elevation angle. The scene center sun elevation angle is provided in the metadata
θ_{SZ} = Local solar zenith angle; $\theta_{SZ} = 90° - \theta_{SE}$

Once NVDI is calculated, it is used to determine the proportion of vegetation, P_V, on the land surface being analyzed, and from that proportion, the land surface emissivity, ε, can be derived.

$$(7) \quad P_V = \left(\frac{NDVI - NDVI_{min}}{NDVI_{max} - NDVI_{min}}\right)^2$$

$$(8)^6 \quad \varepsilon = 0.004 P_V + 0.986$$

The final variable required for the SWA is transmissivity, which is a function of atmospheric vapor content. To estimate this, the US Standard (1976) linear model was employed to determine transmissivity for LandSat 8 bands 10 and 11.

$$(9) \quad \tau = a(ICW) + b$$

where,

a_{10} = -0.1146
b_{10} = 1.0286
a_{11} = -0.1568

[6] Suresh. S, et al. "Estimation of Land Surface Temperature of High Range Mountain Landscape of Devikulam Taluk Using LandSat 8 Data." IJRET: International Journal of Research in Engineering and Technology, Volume 05, Issue 01, January 2016, 92-96, http://esatjournals.net/ijret/2016v05/i01/IJRET20160501017.pdf. Accessed 6 Dec. 2016.

b_{11} = 1.0083
ICW = integrated columnar water, assumed to be 2 g/cm^2.[7]

RESULTS

The estimated land surface temperature is shown in Figure 1 below.

Stack Temperature (K)	373.2

Attachment H6
Calculation of 30-day Rolling Average Emission Limit – Boilers

Eastman Chemical Company supplied hourly emissions data for B-83 and B-325 boilers for the period beginning at midnight on July 1, 2019, and ending at 11:00 PM on December 31, 2020 (see Attachment E1). For each hour in the data set, the individual emission rates for each boiler (18-24 and 30-31) were added to calculate a total emission rate for all affected boilers. Using this total, a series of 30-day rolling average emissions (total for all boilers) was calculated from the hourly averages as the arithmetic average of the current hour, plus the previous 719 hours.

For the set of hourly and 30-day rolling average emission rates, the PERCENTILE.EXC function in Microsoft Excel was used to calculate the 99th percentile values for both the hourly emission rates and the 30-day rolling averages. The compliance ratio for all boilers was calculated as follows:

$$\text{Compliance Ratio} = \frac{99^{th}\text{ Percentile (Hourly)}}{99^{th}\text{ Percentile (30-day Rolling Average)}}$$

The modeled emission rate (1,600 lb/hr) was multiplied by the compliance ratio to determine an allowable emission rate of 1,248 lb/hr.

Allowable Emission Rate (30-day rolling average) = (Modeled Emission Rate)(Compliance Ratio)
Allowable Emission Rate (30-day rolling average) = (1,600 lb/hr)(0.78)
Allowable Emission Rate (30-day rolling average) = (1,248 lb/hr)

Attachment H7
Calculation of 30-day Rolling Average Emission Limit – Incinerators

Eastman Chemical Company supplied hourly emissions data for B-248-1 (rotary kilns) and B-248-2 liquid chemical incinerators for the period beginning at midnight on January 1, 2019, and ending at 11:00 PM on December 31, 2020 (see Attachments F2 and F3). 30-day rolling average emissions were calculated from the hourly averages as the arithmetic average of the current hour, plus the previous 719 hours.

For the set of hourly and 30-day rolling average emission rates, the PERCENTILE.EXC function in Microsoft Excel was used to calculate the 99th percentile values for both the hourly emission rates and the 30-day rolling averages. The compliance ratio for all boilers was calculated as follows:

$$\text{Compliance Ratio} = \frac{99^{th}\text{ Percentile (Hourly)}}{99^{th}\text{ Percentile (30-day Rolling Average)}}$$

The modeled emission rates were multiplied by the compliance ratios to determine an allowable emission rate for each incinerator.

Allowable Emission Rate (30-day rolling average) = (Modeled Emission Rate)(Compliance Ratio)

	B-248-1	**B-248-2**
Data Period	1/1/2019 through 12/31/2020	
Critical Emission Value (CEV)	20 lb/hr	10 lb/hr
Compliance Ratio	0.76	0.2
Allowable Emission Rate (30-day rolling avg.)	15.2	2.0

Attachment I1

Description of Flare Modeling

To assess the adequacy of the proposed limit for Eastman's coal gasification flare (16.28 lb/hr, 30-day rolling average basis), Tennessee reviewed hourly flare emissions for calendar years 2017 through 2023, calculated the number of 30-day rolling averages exceeded the proposed limit, and performed a set of model runs using hourly flare emissions (**Attachment G**) from each calendar year and permitted allowable or uncontrolled potential emissions for the other sources within the nonattainment area. Because the flare is located in the vicinity of both the B-325 powerhouse and the Happy Hill ambient monitor, we used an existing model run (2023-0120-6) for emission sources other than the flare, because B-325 emissions were maximized (Boiler 31 down, Boiler 30 operating at 366.4 lb/hr [permitted allowable divided by the compliance ratio]) and because the highest modeled impact for this run was observed in the vicinity of the flare.

The model outputs are shown in **Table I1-1**. For all years (2019, 2020, and 2021) in which there were no exceedances of the proposed emission rate, the model indicated that all receptors attained the NAAQS, while the modeled impact exceeded the NAAQS three of the four years with exceedances of the proposed limit (2018, 2022, and 2023). One year (2017) had multiple exceedances of the 30-day rolling average emission limit but no modeled exceedances of the standard.

Table I1-1: Model Outputs

Year	Number of 30-day Rolling Averages > 16.28 lb/hr	Number of Hours > 16.28 lb/hr	Modeled Impact (ppb)
2017	30	320	67.12
2018	30	72	75.14
2019	0	31	67.12
2020	0	88	67.12
2021	0	55	67.12
2022	37	226	80.29
2023	30	72	80.93

Eastman's coal gasification operation (MSOP-17, PES B-351-5, Vents B and C)[1] typically operates with no SO_2 emissions, but emissions of hydrogen sulfide and other gases may be controlled by flaring during periods of startup, shutdown, malfunction, or during other process upsets.

EPA's SIP guidance states that adjustment of modeled hourly emissions to a longer-term average of up to 30 days is an appropriate control strategy. The 30-day rolling average is calculated from a representative baseline of hourly emission rates and the modeled emission rate, as shown in **Equation 1.** The ratio of 99th percentile hourly and 30-day rolling average emission rates is the "compliance ratio." The 30-day rolling average allowable emission rate was calculated as shown in **Table I1-2** for the coal gasification flare.

[1] Eastman's coal gasification plant includes the gasifiers, which produce a combined stream of carbon monoxide and hydrogen for downstream processing, and a sulfur recovery plant, which converts sulfur compounds (hydrogen sulfide and other trace gases) to elemental sulfur for sale. The flare may be used to control emissions from the gasifiers or the sulfur recovery plant during periods of startup, shutdown, or malfunction, and when the sulfur recovery plant is not vented to the flare, only carbon monoxide and hydrogen gases are combusted.

$$\text{30-day rolling average} = (\text{modeled emission rate}) \left(\frac{(99^{th} \text{ percentile 30-day rolling average emission rate})}{(99^{th} \text{ percentile hourly emission rate})} \right)$$ **Equation 1**

Table I1-2: Calculation of 30-Day Rolling Average Emission Limit, Coal Gasification Flare	
Period of representative emissions	January 1, 2021, through December 31, 2023
99^{th} percentile hourly emission rate	30.4 lb/hr
99^{th} percentile 30-day rolling average emission rate	41.6 lb/hr
Compliance ratio	1.4
Modeled emission rate	16.28 lb/hr
Allowable emission rate	16.28 lb/hr, 30-day rolling average

Because the flare emits no SO_2 during normal operations, use of the procedure from EPA's 2014 SO_2 SIP guidance results in a long-term average emission rate that is higher than the modeled emission rate. Tennessee established a long-term average emission rate using a compliance ratio of 1.0 to minimize the possibility of long-term emissions exceeding the modeled emission rate[2]. Tennessee also established a supplemental limit of 48 tons/year to minimize operation of the flare at or above the critical emission value.

[2] If a compliance ratio of 1.4 was used, the 30-day rolling average limit would be 22.8 lb/hr.

Attachment I2

Calculation of Flare Compliance Ratio

Excludes all shutdown hours with zero emissions
